**Abstract :** The signal to be modeled consists of parameters, using which the original signal can be reconstructed or recovered. When once it is possible to accurately model a signal, then it becomes possible to perform important signal processing tasks such as signal compression, interpolation, prediction. The models used are AR (Auto Regressive) or All-Pole model, MA (Moving Average) or All-Zero model, ARMA (Auto Regressive Moving Average) or Pole-Zero model. Various methods have been suggested for the coefficients determination among which are Prony, Pade, Shank, Autocorrelation, Covariance techniques. This paper aims at AR modeling which is applied to these techniques on speech signals and comparisons are carried out. The comparisons are entirely based on the value of the coefficients obtained.

**IndexTerms - Pade, Prony, Shank, Auto Regressive. .**

## I. INTRODUCTION

The use of modeling technique to predict or reconstruct a data sequence is concerned with the representation of data in an efficient technique [1]–[4], [6], [10]. Signal modeling have been used in radar application, geophysical application, Medical signal processing, ultrasonic tissue backscatter coefficient estimation, speech processing, music understanding and more recently in the field of Magnetic Resonance Imaging (MRI) reconstruction [2], [4], [6], [10].

Signal modeling involves two steps [2], these are;

- 1) Model selection: Choosing an appropriate parametric form for the model data
- 2) Model Parameter determination: This includes model order and model coefficients determination.

Despite the success reported in the use of modeling technique, two important problems constitutes challenges to the applicability of this method, these are:

- 1) Estimation of Model order: There have been various efforts in determining workable criteria for the determination of an appropriate model order. The use of a model with an order too high over fits the data while the use of a model with a low order leads to insensitivity to noise [2], [4], [6].
- 2) Estimation of model coefficient: The second important challenges militating against the use of modeling technique is the estimation of the model coefficients. Some of the existing methods of determining model coefficients includes Least Squares, Pade, Prony, Shank, Autocorrelation, Auto covariance methods [9].

## II. SIGNAL MODELING TYPES

A linear system's transfer function  $H(z)$  is given by

$$H(z) = \frac{B_q(z)}{A_p(z)} = \frac{\sum_{k=0}^q b_q(k)z^{-k}}{1 + \sum_{k=1}^p a_p(k)z^{-k}} \quad (1)$$

Different models related to deterministic signals have three specific models:

1. Auto Regressive (AR) Process.
2. Moving Average (MA) Process.
3. Auto Regressive Moving Average (ARMA) Process.

### • Auto Regressive (AR) Process

In this case, only poles will be present i.e. the linear filter  $H(z) = 1/A_p(z)$ . Hence, this process is also called as an all pole filter.

The system function of AP process is given by,

$$H(z) = \frac{1}{A_p(z)} = \frac{1}{1 + \sum_{k=1}^p a_p(k)z^{-k}} \quad (2)$$

**fig. 1:** block diagram of AR process

### Mathematical Modeling of AR Process

From Fig. 1, the output  $x(n)$  is the convolution of the input signal  $\delta(n)$  and the system function of the filter  $h(n)$  i.e.

$$x(n) = \delta(n) * h(n) \tag{3}$$

$$X(z) = 1 \cdot H(z) = \frac{1}{A_p(z)} \tag{4}$$

$$X(z) \cdot A_p(z) = 1 \tag{5}$$

$$X(z) \left[ 1 + \sum_{k=1}^p a_p(k) z^{-k} \right] = 1 \tag{6}$$

$$x(n) + \sum_{k=1}^p a_p(k) x(n-k) = \delta(n) \tag{7}$$

$$x(n) = \delta(n) - \sum_{k=1}^p a_p(k) x(n-k) \tag{8}$$

**• Modeling Procedure**

The goal of signal modeling is to produce a signal which should be as close as possible to with input to the filter as impulse signal [1].

fig 2: modeling procedure

Any deterministic signal can be generated by linear time invariant filter driven with unit impulse function  $\delta(n)$ . This is shown in fig.2.

The steps followed for modeling a signal are:

1. Generation of analog signal.
2. Discretization of the signal.
3. In this step,  $H(z)$  is found out using different method.
4.  $H(z)$  is driven with  $\delta(n)$  then the signal obtained approximate the signal

**III. METHODS OF COEFFICIENTS DETERMINATION**

Various methods have been reported in literatures for determining the AR model coefficients among which are:

**A. Direct least square method**

The block diagram for direct method of least square solution is as shown in Fig. 1 the modeling error can be written as

$$e'(n) = x(n) - h(n)$$

$$\mathcal{E}_{LS} = \sum_{n=0}^{\infty} |e'(n)|^2 \tag{10}$$

A necessary condition for the filter coefficients to minimize the squared error is to calculate the partial derivative of  $\mathcal{E}_{LS}$  with respect to each of the coefficients  $a_p^*(k)$  &  $b_q^*(k)$  vanish, i.e.

$$\frac{\partial \mathcal{E}_{LS}}{\partial a_p^*(k)} = 0 ; k = 1, 2, K p \tag{11}$$

$$\frac{\partial \mathcal{E}_{LS}}{\partial b_q^*(k)} = 0 ; k = 1, 2, K q \tag{12}$$

Using Parseval's theorem, the least squares error may be written in frequency domain as

$$\mathcal{E}_{LS} = \frac{1}{2\pi} \int_{-\pi}^{\pi} |E'(e^{j\omega})|^2 d\omega$$

To find the denominator coefficients  $a_p(k)$ , set the partial derivative of  $\mathcal{E}_{LS}$  with respect to  $a_p(k)$ , equal to zero

$$\frac{\partial \mathcal{E}_{LS}}{\partial a_p^*(k)} = \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{\partial}{\partial a_p^*} [E'(e^{j\omega}) E'^*(e^{j\omega})] d\omega = 0 \tag{13}$$

Since,  $E'(e^{j\omega}) = X(e^{j\omega}) - \frac{B_q(e^{j\omega})}{A_p(e^{j\omega})}$  (14)

On substitution of Eq. (14), the Eq. (13) becomes

$$\frac{\partial \mathcal{E}_{LS}}{\partial a_p^*(k)} = \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ X(e^{j\omega}) - \frac{B_q(e^{j\omega})}{A_p(e^{j\omega})} \right] \frac{B_q^*(e^{j\omega})}{[A_p^*(e^{j\omega})]^2} e^{jk\omega} d\omega = 0 \quad (15)$$

for  $k = 1, 2, \dots, p$

Similarly, to find the numerator coefficients set the partial derivative of  $\mathcal{E}_{LS}$  with respect to  $b_q^*(k)$  equal to zero

$$\frac{\partial \mathcal{E}_{LS}}{\partial b_q^*(k)} = \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{\partial}{\partial b_q^*(k)} \left[ E'(e^{j\omega}) E'^*(e^{j\omega}) \right] d\omega = 0 \quad (16)$$

Since,

$$E'(e^{j\omega}) = X(e^{j\omega}) - \frac{B_q(e^{j\omega})}{A_p(e^{j\omega})} \quad (17)$$

On substitution of Eq. (17) in Eq. (16), the Eq. (16) becomes

$$\frac{\partial \mathcal{E}_{LS}}{\partial b_q^*(k)} = -\frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ X(e^{j\omega}) - \frac{B_q(e^{j\omega})}{A_p(e^{j\omega})} \right] \frac{e^{jk\omega}}{A_p^*(e^{j\omega})} d\omega = 0 \quad (18)$$

for  $k = 1, 2, \dots, q$

But, it is clear that from the Eq. (15) and (18) that the optimum set of model parameters are defined implicitly in terms of a set of  $p+q+1$  nonlinear equations.

**• Limitation**

The limitation with least squares method is that the equations results to a set of non-linear equations. Therefore, this approach is not mathematically tractable and not amenable in real-time signal processing applications.

**B. Pade Approximation**

The development of Pade method begins by expressing the system function as,

$$H(z) = \frac{B_q(z)}{A_p(z)} = \frac{\sum_{k=0}^q b_q(k) z^{-k}}{\sum_{k=1}^p a_p(k) z^{-k}}$$

which leads to the difference equation

$$h(n) + \sum_{k=1}^p a_p(k) h(n-k) = b_q(n) \quad (19)$$

To find the coefficients  $a_p(k)$  &  $b_q(k)$  that give an exact fit of the data to model over the interval  $[0, p+q]$ , equate  $h(n)$  and  $x(n)$  then the Eq. (19) changes to

$$x(n) + \sum_{k=1}^p a_p(k) x(n-k) = \begin{cases} b_q(n) & ; n = 0, 1 \dots q \\ 0 & ; n = q+1, q+2 \dots p+q \end{cases} \quad (20)$$

**• Limitation**

There is no guarantee on how accurate the model will be for values of  $n$  outside the interval  $[0, p+q]$ . In some cases, the match may be very good, while in others it may be poor.

**C. Prony method**

The block diagram of Prony’s method of signal modeling is shown in Fig. 3. The modeling error defined as the difference between the input and the output of the filter is given by

$$e'(n) = x(n) - h(n) \quad (21)$$

$$E'(z) = X(z) - H(z) = X(z) - \frac{B_q(z)}{A_p(z)}$$

fig: 3: system interpretation of prony’s method for signal modeling.

Multiplying both sides of Eq. (21) with  $A_p(z)$  a new error is obtained as

$$E(z) = A_p(z) E'(z) = A_p(z) X(z) - B_q(z) \quad (22)$$

and in time-domain Eq. (22) is given by

$$e(n) = a_p(n) * x(n) - b_q(n) = \hat{b}_q(n) - b_q(n) \quad (23)$$

Since  $b_q(n) = 0$  for  $n > q$ , the error is expressed as,

$$e(n) = \begin{cases} x(n) + \sum_{l=1}^p a_p(l)x(n-l) - b_q(n) & ; n = 0, 1, q \\ x(n) + \sum_{l=1}^p a_p(l)x(n-l) & ; n > q \end{cases} \quad (24)$$

$$\mathcal{E}_{p,q} = \sum_{n=q+1}^{\infty} |e(n)|^2 \quad (25)$$

Setting the partial derivatives of  $\mathcal{E}_{p,q}$  with respect to  $a_p^*(k)$  equal to zero, gives

$$\frac{\partial \mathcal{E}_{p,q}}{\partial a_p^*(k)} = \sum_{n=q+1}^{\infty} \frac{\partial [e(n)e^*(n)]}{\partial a_p^*(k)} = 0 \quad (26)$$

$$\sum_{n=q+1}^{\infty} e(n) \left[ \frac{\partial x^*(n)}{\partial a_p^*(k)} + \sum_{k=1}^p \left[ \frac{\partial a_p(l)x^*(n-k)}{\partial a_p^*(k)} \right] \right] = 0$$

Since the partial derivative of  $e^*(n)$  with respect to  $a_p^*(k)$  is  $x^*(n-k)$  Eq. (3.31) becomes

$$\sum_{n=q+1}^{\infty} e(n)x^*(n-k) = 0 \quad ; \quad \text{for } k=1,2,\dots,p$$

Substitute Eq. (24) for  $e(n)$  into Eq. (26),

$$\sum_{n=q+1}^{\infty} \left\{ x(n) + \sum_{l=1}^p a_p(l)x(n-l) \right\} x^*(n-k) = 0$$

$$\sum_{l=1}^p a_p(l) \left[ \sum_{n=q+1}^{\infty} x(n-l)x^*(n-k) \right] = - \sum_{n=q+1}^{\infty} x(n)x^*(n-k)$$

$$\sum_{k=1}^p a_p(k)r_x(k,l) = -r_x(k,0) ; \text{ for } k=1,2,\dots,p \quad (27)$$

$$r_x(k,l) = \sum_{n=q+1}^{\infty} x(n-l)x^*(n-k)$$

**D. Shank method (Modified Prony)**

Shank method is a modified Prony method in the sense that the moving average coefficients is obtained by finding the least square minimization of the model error over the entire data length [9]. The model can be viewed as a cascade of two filters,  $B_q(z)$  and  $A_p(z)$ .

fig. 4: system interpretation of shank’s method for signal modeling.

The cascade of two filters  $A_p(z)$  and  $B_q(z)$  are shown in the fig.4 and its system function is given by

$$H(z) = B_q(z) \left\{ \frac{1}{A_p(z)} \right\} \quad (28)$$

From fig. 4, the unit sample response  $g(n)$  of the first filter  $1/A_p(z)$  is determined with  $g(n) = 0$  for  $n < 0$

$$g(n) = \delta(n) * a_p(n)$$

$$g(n) = \delta(n) - \sum_{k=1}^p a_p(k)g(n-k) \quad (29)$$

The minimum squared error is defined as

$$\mathcal{E}_s = \sum_{n=0}^{\infty} |e'(n)|^2$$

Minimizing the error in Prony method gives

$$\sum_{l=0}^q b_q(l)r_g(k-l) = r_{xg}(k) ; k = 0,1,\dots,q$$

$$r_g(k-l) \equiv r_g(k,l) = \sum_{n=0}^{\infty} g(n-l)g^*(n-k) \quad (30)$$

$$r_{xg}(k) = \sum_{n=0}^{\infty} x(n)g^*(n-k)$$

#### IV. APPLICATION OF SIGNAL MODELING TO SPEECH SIGNALS

Speech coding or speech compression is the field concerned with obtaining compact digital representations of speech signals for the purpose of efficient transmission or storage. The aim in speech coding is to represent speech by a minimum number of bits while maintaining its perceptual quality [4].

fig. 5: general block diagram for application of digital signal processing to speech signals

The block diagram in Fig. 5 represents any system where time signals such as speech are processed by the techniques of DSP. This figure simply depicts the notion that once the speech signal is sampled, it can be manipulated in virtually limitless ways by DSP techniques.

#### • Basic Procedure of Signal Modeling

Any deterministic signal can be generated by linear time-invariant filter driven with impulse function. The procedure of signal modeling to be followed when applied to speech signals are as follows:

1. Discretization of analog speech signal.
2. Application of modeling methods to the speech signal (model parameters are obtained).
3. The transfer function of the filter  $H(z)$  is driven with impulse signal  $\delta(n)$ , and then the original speech signal is obtained.

#### V.SIMULATION & RESULTS

#### • Application of Speech Signals to Signal Modeling Methods: Pade Approximation Method

First, the speech signal which is in the continuous or analog form is considered. Then the numerator and denominator coefficients are calculated by applying the discrete speech signal to Pade approximation method algorithm. Applying the impulse signal as the input to the filter and using these coefficients, the output signal of the filter  $y(n)$  is obtained. The error signal is calculated as the difference between the input signal  $x(n)$  and output signal  $y(n)$ . In order to get the signal  $y(n)$  as close as possible to the signal  $x(n)$ , the number of poles and zeros in the algorithm have to be varied.

#### AR Model

The input is considered to be a speech signal with filename speech\_10k. The number of poles is considered to be  $p = 205$ . The

Fig. 6 shows the original, estimated (or reconstructed) speech signals and the error

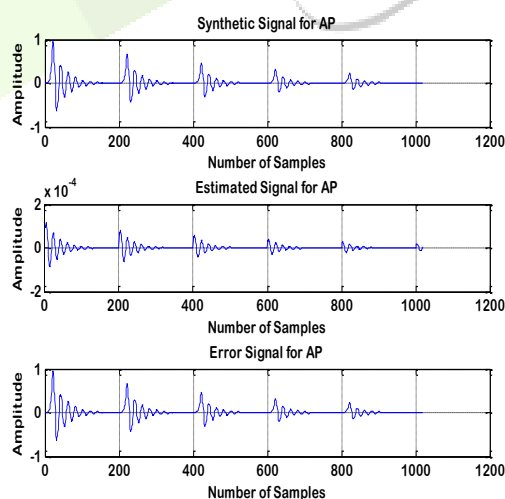

fig. 6: signal modeling using pade approximation method for ap model.

#### Prony's Method

First, the speech signal which is in the continuous or analog form is considered. Then the numerator and denominator coefficients are calculated by applying the speech signal to Prony's method algorithm. Applying the impulse signal as the input to the filter and using these coefficients, the output signal of the filter  $y(n)$  is obtained. The error signal is calculated as the difference between the input signal  $x(n)$  and output signal  $y(n)$ . In order to get the signal  $y(n)$  as close as possible to the signal  $x(n)$ , the number of poles and zeros in the algorithm have to be varied.

**AR Model**

The input is considered to be a speech signal with filename speech\_10k. The number of poles is considered to be  $p = 1$ . The Fig. 7 shows the original, estimated (or reconstructed) speech signals and the error obtained.

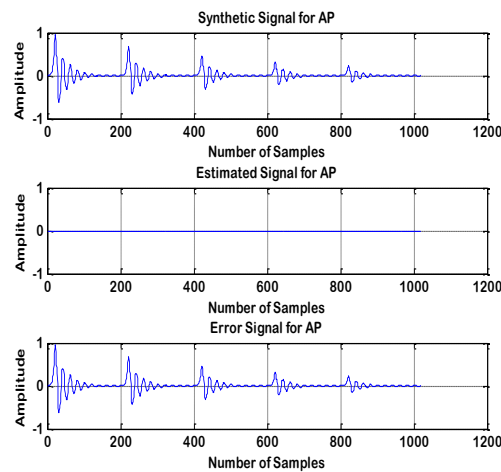

fig. 7: signal modeling using prony's method for ap model.

**Shank's Method**

First, the speech signal which is in the continuous or analog form is considered. Then the numerator and denominator coefficients are calculated by applying the speech signal to Shank's method algorithm. Applying the impulse signal as the input to the filter and using these coefficients, the output signal of the filter  $y(n)$  is obtained. The error signal is calculated as the difference between the input signal  $x(n)$  and output signal  $y(n)$ . In order to get the signal  $y(n)$  as close as possible to the signal  $x(n)$ , the number of poles and zeros in the algorithm have to be varied.

**AR Model**

The input is considered to be a speech signal with filename speech\_10k. The number of poles is considered to be  $p = 205$ . The Fig. 8 shows the original, estimated (or reconstructed) speech signals and the error obtained.

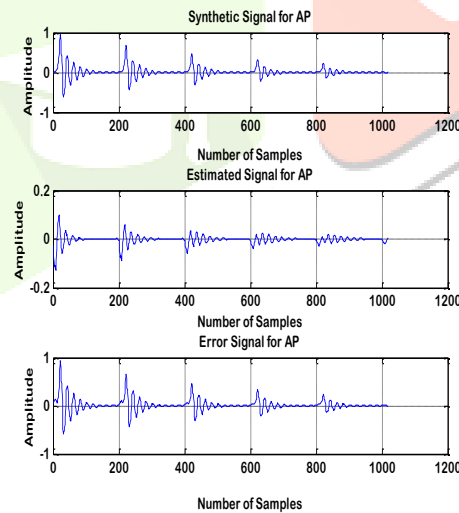

fig. 8: signal modeling using shank's method for ap model.

The Table 1 shows the simulated results of deterministic speech signals when applied to different methods of signal modeling. From the tabulated results, we can observe that Shank's method of signal modeling produces accurate reconstructed signal i.e. error produced is minimum.

table 1: simulated results of signal modeling methods when applied to speech signals.

Method	Error AP Model
Pade Approximation Method	5.9985
Prony's Method	6.0006
Shank's Method	5.6528

## VI. CONCLUSION

The speech signals are implemented using deterministic signal modeling methods. The purpose of all these methods is to find the model parameters and again reconstruct the original signal using those parameters. The simulated results proved that the Shank's method has the ability to estimate accurately as compared to other methods.
