### Abstract

The FT-IR Raman spectra of 4-(phenylmethyl) phenol (4PMP) have been recorded in the region 4000–400  $\text{cm}^{-1}$  and 3500–100  $\text{cm}^{-1}$  respectively. The total energy calculations of 4pmp were tried for the possible conformers. The molecular structure, geometry optimization, vibrational frequencies were obtained by the density functional theory (DFT) using B3LYP method with 6-31+G (d) and 6311++G (d, p) basis sets. The complete assignments were performed on the basis of the potential energy distribution (PED) of the vibrational modes, calculated and the scaled values were compared with experimental FT-IR and FT-RAMAN spectra. The observed and the calculate frequencies are found to be in good agreement. A Mulliken's atomic charge analysis has also been made on optimized geometries of 4pmp in gas phase. Information about the size, shape charge density distribution and site of decimal respectively of the molecules has been obtained by mapping electron density surface with molecular electrostatic potential (MEP).

### I. INTRODUCTION

The electro negative atom such as halogen attached to the (phenylmethyl) phenol in a highly reactive the phenyl methylphenol. The 4-(phenylmethyl) phenol is a white crystalline powder with molecular formula ( $\text{C}_{13}\text{H}_{12}\text{O}$ ). The vibration spectroscopic using DFT methods have reported on methyl phenol. Therefore the present investigation was undertaken study the vibration of FT-IR, FT-Raman spectra of the molecule completely and to identify the vibrations normal modes with grater wave number accuracy. Predication of vibration frequency of polyatomic molecules by quantum chemical calculation has become very popular because of accurate and consistent description of the experimental data. 4pmp was investigated by using B3LYP calculation with 6-31+G (d) and 6-311++G (d, p) basis sets.

### II. EXPERIMENTAL DETAILS

The pure sample of 4PMP in the light yellow waxy solid form was purchased from the Lancaster Chemical Company (UK), with a stated purity of greater than 98% and it was used as such without further purification. The FT-IR spectrum of this compound was recorded in the region 4000–400  $\text{cm}^{-1}$  on IFS 66V spectrometer equipped with an MCT detector using KBr beam splitter and globar source. The FT-Raman spectrum of title molecule has been recorded using the 1064 nm line of a Nd:YAG laser as excitation wavelength in the region 3500–100  $\text{cm}^{-1}$  on a BRUKER model RFS 66V spectrometer. The reported wavenumbers are expected to the accurate within  $\pm 1 \text{ cm}^{-1}$  resolution with 250 mW of power at the sample in both the techniques.

### III. COMPUTATIONAL DETAILS

The entire calculations was performed at DFT/B3LYP method with 6-31+G(d) and 6-31++G(d, p) levels with the standard basis set 6-311G++ (d, p) on personal computer using GAUSSIAN 09W [1] program package, invoking gradient geometry optimization [2]. The global minimum energy conformer is used in the vibrational wavenumber calculation at the B3LYP and with using 6-311G (d, p) level. Subsequently, the vibrational in association with the molecule were derived along with their IR intensity and Raman activity. In order to fit the theoretical wavenumbers to the experimental, the scaling factors have been introduced by using a least square optimization method. The polarizability, hyperpolarizability and dipole moments of 4PMP have been calculated using the same method. The HOMO–LUMO analysis has been carried out to explain the charge transfer within the molecule. The global hardness ( $\eta$ ), global softness ( $\nu$ ), electronegativity ( $\chi$ ) and chemical potential ( $\mu$ ) have been calculated using the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO). The natural bonding orbital's (NBO) calculations [3] were performed using NBO 3.1 program as implemented in GAUSSIAN 09W package at DFT level in order to understand various second order interactions between the another subsystem, which is a measure of the intramolecular delocalization or hyper-conjugation. To check whether the chosen set of symmetric coordinates contribute maximum to the potential energy associated with the molecule, the PED has been carried out. The transformation of force field, subsequent normal coordinate analysis and calculation of the PED were done on a PC with the MOLVIB program (Version 7.0 – G77) written by Sundius [4]. The complete information's regarding population of electrons in sub-shells of atomic orbital's and electron densities of an atom in the title molecule.

#### Prediction of Raman Intensity

The Raman activities ( $S_i$ ) calculated with the GAUSSIAN 09W Program were converted to Raman intensities ( $I_i$ ) using the following relationship derived from the intensity theory of Raman scattering [5, 6].

$$I_i = \frac{f(\nu_0 - \nu_i)^4 S_i}{\nu_i [1 - \exp(-hc\nu_i/kT)]}$$

where  $\nu_0$  is the laser exciting frequency in  $\text{cm}^{-1}$  (in this work, we have used the excitation wavenumber  $\nu_0=9398.5 \text{ cm}^{-1}$ , which corresponds to the wavelength of 1064 nm of a Nd:YAG laser),  $\nu_i$  is the vibrational wavenumber of the  $i^{\text{th}}$  normal mode (in  $\text{cm}^{-1}$ ) and  $S_i$  is the Raman scattering activity of the normal mode  $\nu_i$ ,  $f$  (is the constant equal to  $10^{-12}$ ) is a suitably chosen common normalization factor for all peak intensities.  $h$ ,  $k$ ,  $c$ , and  $T$  are Planck constant, Boltzmann constant, speed of light, and temperature in Kelvin, respectively.

#### Nonlinear Optical Effects

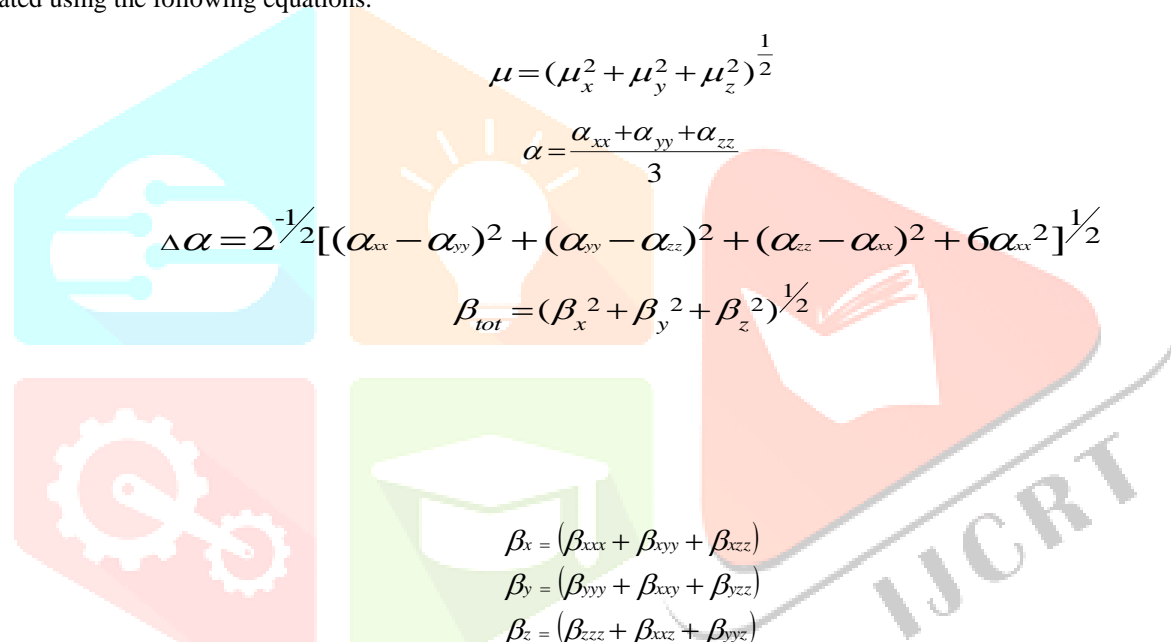

The nonlinear optical effects arise due to the interactions of electromagnetic fields in various media to produce new fields which are altered in frequency, phase and amplitude or other propagation characteristics from the incident fields [7]. Computational approach is an inexpensive, yet an effective way to design molecules by analyzing their potential which helps to determine the molecular NLO properties. In this direction, quantum chemical calculations of the title compound were carried out using GAUSSIAN 09W package employing the B3LYP functional supplemented with standard 6-31+G (d) and 6-311++G(d, p) basis set. The first static hyperpolarizability ( $\beta_{\text{tot}}$ ) and its related properties ( $\alpha$ ,  $\beta$  and  $\Delta\alpha$ ) of 4PMP have been calculated using B3LYP/6-31+G (d, p) and /6-311++G (d, p) methods based on finite-field approach and are presented in Table 1. To calculate all the electric dipole moment and the first hyperpolarizability tensor components for a given system will depend on the choice of the Cartesian co-ordinate system (x, y, z)=(0, 0, 0) was chosen at own centre of mass of molecule. The polarizability of this novel molecular system for which  $\alpha_{xx} = \alpha_{yy} = \alpha_{zz}$  is said to be isotropic. The polarizability is isotropic or is the same in all directions for a molecular system whose electron density is spherically symmetrical. If the molecule is perfectly isotropic ( $P$ ) and ( $E$ ) will have

the same direction and is then a simple scalar quantity. The polarizability of this novel molecular system for which  $\alpha_{xx} \neq \alpha_{yy} \neq \alpha_{zz}$  ( $P$ ) will no longer have the same direction as ( $E$ ).

In the presence of an applied electric field, the energy of a system is a function of the electric field and the first order hyperpolarizability is a third rank tensor that can be described by a  $3 \times 3 \times 3$  matrices. The 27 components of the 3D matrix can be reduced to 10 components because of the Kleinman symmetry [8]. It can be given in the lower tetrahedral format. It is obvious that the lower part of the  $3 \times 3 \times 3$  matrices is tetrahedral. The components of  $\beta$  are defined as the coefficients in the Taylor series expansion of energy in an external electric field. The external electric field is weak and homogeneous, this expansion becomes

$$E = E^0 - \frac{\mu_i F_i}{1!} - \frac{\alpha_{ij} F_i F_j}{2!} - \frac{\beta_{ijk} F_i F_j F_k}{3!} - \frac{\gamma_{ijkl} F_i F_j F_k F_l}{4!} + \dots$$

where  $E^0$  is the energy of the unperturbed molecules,  $F_i$  is the field at the origin and  $\mu_i$ ,  $\alpha_{ij}$ ,  $\beta_{ijk}$  and  $\gamma_{ijkl}$  are the components of dipole moment, polarizability and the hyperpolarizability, respectively. The total static dipole moment ( $\mu$ ), the mean polarizability ( $\alpha$ ), the anisotropy of the polarizability ( $\Delta\alpha$ ) and the mean first hyperpolarizability ( $\beta_{tot}$ ), using the  $x$ ,  $y$ ,  $z$  components can be calculated using the following equations:

$$\mu = (\mu_x^2 + \mu_y^2 + \mu_z^2)^{\frac{1}{2}}$$

$$\alpha = \frac{\alpha_{xx} + \alpha_{yy} + \alpha_{zz}}{3}$$

$$\Delta\alpha = 2^{-\frac{1}{2}} [(\alpha_{xx} - \alpha_{yy})^2 + (\alpha_{yy} - \alpha_{zz})^2 + (\alpha_{zz} - \alpha_{xx})^2 + 6\alpha_{xx}^2]^{\frac{1}{2}}$$

$$\beta_{tot} = (\beta_x^2 + \beta_y^2 + \beta_z^2)^{\frac{1}{2}}$$

where

$$\beta_x = (\beta_{xxx} + \beta_{xyy} + \beta_{xzz})$$

$$\beta_y = (\beta_{yyy} + \beta_{xyy} + \beta_{yzz})$$

$$\beta_z = (\beta_{zzz} + \beta_{xxz} + \beta_{yyz})$$

Since the values of the polarizabilities ( $\Delta\alpha$ ) and the hyperpolarizabilities ( $\beta_{tot}$ ) of the GAUSSIAN 09 output are obtained in atomic units (a.u.), the calculated values have been converted into electrostatic units (e.s.u.) (1 a.u.= $8.3693 \times 10^{-33}$  e.s.u.). The total molecular dipole moment and first order hyperpolarizability are 1.4985 and 1.4792 Debye, and  $0.508 \times 10^{-30}$  and  $0.545 \times 10^{-30}$  e.s.u., respectively and are depicted in Table 1. Urea is one of the prototypical molecules used in the study of the NLO properties of molecular systems and frequently used as a threshold value for comparative purposes. First order hyperpolarizability of the title molecule is 1.9 times greater than those of urea ( $\mu$  and  $\beta$  of urea are 1.3732 Debye and  $0.33728 \times 10^{-30}$  e.s.u.) obtained by B3LYP/6-31+G (d) and /6-311++G (d, p) methods. So we conclude that the title molecule is an attractive object for future studies of non-linear optical properties.

Table 1

The electric dipole moment ( $\mu$ ) (debye), the mean polarizability( $\alpha$ )(e.s.u.), anisotropy polarizability( $\Delta\alpha$ )(e.s.u.) and first hyperpolarizability( $\beta_{tot}$ )(e.s.u.) for 4-(phenylmethyl)phenol at B3LYP/6-31+G (d) and B3LYP/6-311++G (d, p) methods.

#### IV. RESULTS AND DISCUSSION

##### Molecular Geometry

The optimized structural parameters such as bond lengths, bond angles and dihedral angles determined by theoretical B3LYP and methods with 6-31+G (d) and 6-311++G(d, p) basis set. The bond lengths and bond angles and dihedral angles were presented in Table 2 in accordance with the atom numbering scheme as given in Fig. 1.

Fig.1. Possible conformational structures of 4-(phenylmethyl) phenol

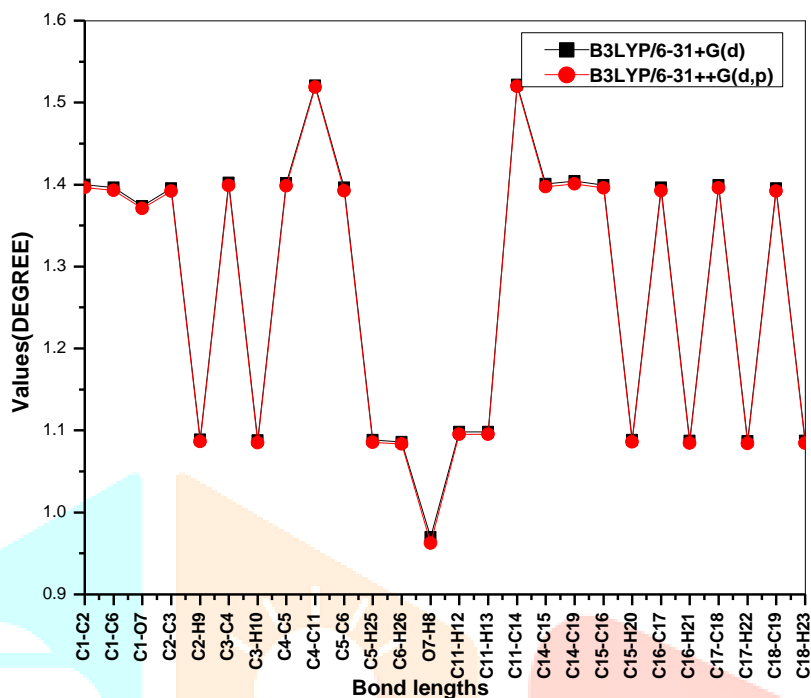

Fig.2. Bond length difference between the theoretical B3LYP/6- 31+G (d) and B3LYP/6-311++G(d, p) of the 4-(phenylmethyl) phenol

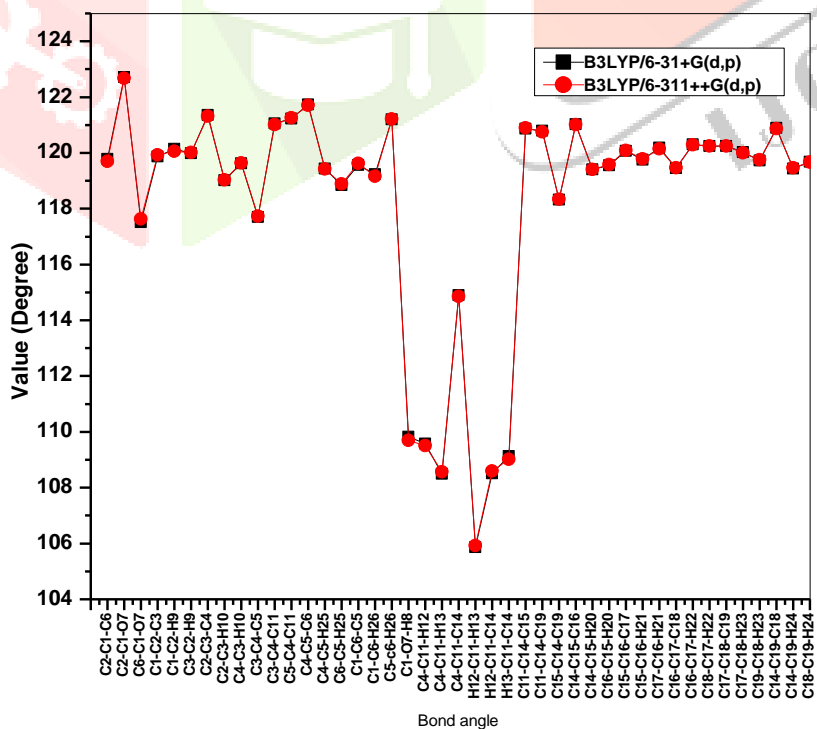

Fig.3. Bond angle differences between experimental and theoretical B3LYP/6-31+G (d) and B3LYP/6-311++G(d, p) of the 4-(phenylmethyl) phenol

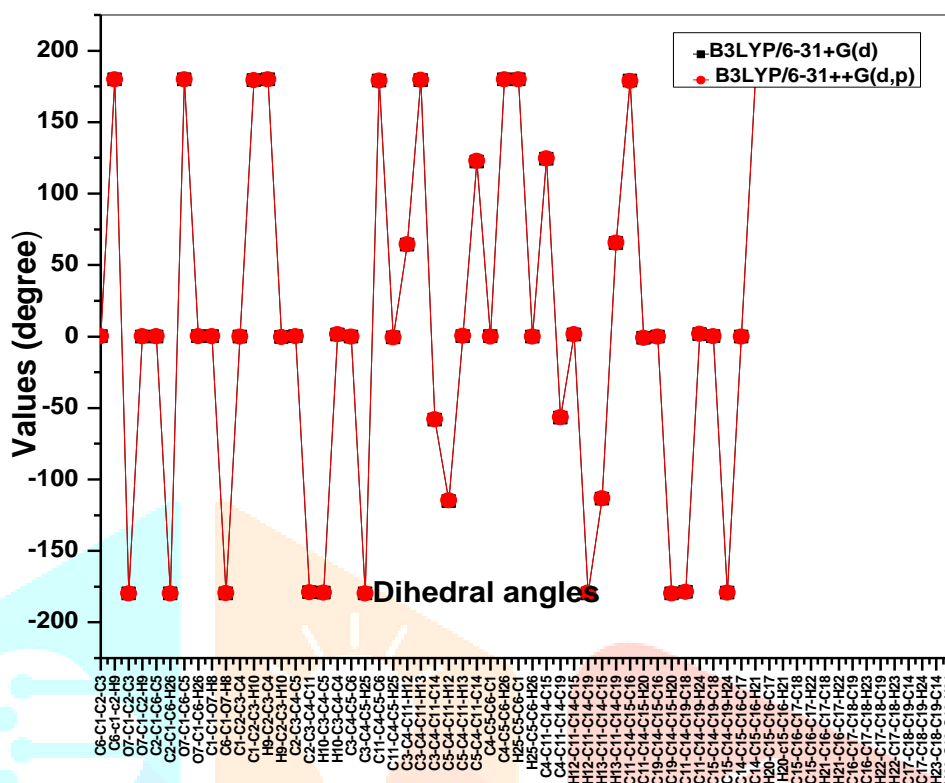

Fig.4. Dihedral angle differences between experimental and theoretical B3LYP/6-31+G(d) and B3LYP/6-311++G(d, p) of the 4-(phenylmethyl) phenol

The computed bond lengths and bond angles are slightly larger and smaller, because the deviation of theoretical calculations are performed upon isolated molecule in the gaseous phase and the experimental results are performed on the solid phase of the molecule. The calculated geometrical parameters by B3LYP/6-31+ G (d) and 6-311++G (d, p) method are very good agreement with method. The C–C aromatic bond distances full in the range from 1.3836 to 1.4057 Å for the B3LYP/6-31+G (d) and 6-311++G (d, p) method, which are in good agreement with those in molecular structure of 4PMP. Figs.2,3,4 respectively.

#### 4.1. Vibrational Analysis

The title molecule consists of 26 atoms, which undergo 72 normal modes of vibrations. On the basis of C<sub>1</sub> symmetry the 72 fundamental vibrations of the title molecule can be distributed into 49 in-plane and 23 out-of-plane vibrations of same species. FT-IR and FT-Raman spectral wavenumbers have been assigned to base on the normal coordinate analysis following the scaled quantum mechanical force field methodology. The output files of the quantum chemical calculations contain the force constant matrix in Cartesian co-ordinates and in Hartree/Bohr<sup>2</sup> units. The force constants are transformed to the force fields in the local symmetry coordinates. The spectroscopic signature of 4PMP, a frequency calculation is performed on the gaseous phase of the molecule, while experimental FT-IR and FT-Raman are performed on the solid phase of the molecule. Hence there are disagreements between calculated and observed vibrational wavenumbers. To overcome discrepancies between observed and calculated wavenumbers, the scaling factors have been introduced by using a least square optimization method. To calculate optimal scaling factors ( $\lambda$ ), we employed at least-square procedure using the following equation [9]

$$\left[ \lambda = \frac{\sum_i^{all} \omega_i^{theory} \nu_i^{expt}}{\sum_i^{all} (\omega_i^{theory})^2} \right]$$

where  $\omega_i^{theory}$  and  $\nu_i^{expt}$  are the  $i^{th}$  theoretical harmonic and  $i^{th}$  experimental fundamental frequencies (in cm<sup>-1</sup>), respectively. Only single (uniform) scaling factors were calculated, without discrimination for different vibrations. The value obtained is 0.9621 for B3LYP and 0.9617 for 6-31+G (d) and 6-311++G (d, p) methods and it is very close to the recommended scaling factor of 0.962. The root mean square (RMS) value is obtained in the study using the following expression:

$$\left[ RMS = \sqrt{\frac{1}{n-1} \sum_i^n (\nu_i^{cal} - \nu_i^{exp})^2} \right]$$

The RMS error between unscaled and experimental frequencies is found 113 cm<sup>-1</sup> by B3LYP/6-31+G (d) and 6-311++G (d, p) 96 cm<sup>-1</sup> by /6-311G++ (d, p) levels. However, for reliable information's on the vibrational properties the use of a selective scaling is necessary. Figs. 5 and 6 present the experimental and calculated FT-IR and FT-Raman spectra for comparative purposes. The resulting vibrational wavenumbers for the optimized geometry and the proposed vibrational assignments as well as IR and Raman intensities are summarized in Table 3.

### Ring Vibrations

Ring vibrational modes are sensitive to substitutions. Owing to aromatic ring vibrations, phenols absorb strongly in the region  $1600\text{--}850\text{ cm}^{-1}$ . The ring stretching vibrations are very prominent, as the double bond is in conjugation with the ring, in the vibrational spectra of benzene and its derivatives [10]. The carbon-carbon stretching vibrations occur in the region of  $1650\text{--}1200\text{ cm}^{-1}$ . In general, the bands are of variable intensity and are observed at  $1625\text{--}1590$ ,  $1590\text{--}1575$ ,  $1540\text{--}1470$ ,  $1465\text{--}1430$  and  $1380\text{--}1280\text{ cm}^{-1}$  from the frequency ranges given by Varsanyi [11] for the five bands in the region. In the present work, the frequencies observed in FT-IR spectrum at  $1616$ ,  $1604$ ,  $1511$ ,  $1465$ ,  $1325$  and  $1220\text{ cm}^{-1}$  have been assigned to C-C stretching vibrations. The corresponding vibration appears in FT-Raman spectrum at  $1614$ ,  $1464$  and  $930\text{ cm}^{-1}$ . Theoretically computed values calculated at  $1628$ ,  $1615$ ,  $1576$  and  $1282\text{ cm}^{-1}$  and by B3LYP/6-31+G (d) and B3LYP/6-311++G (d, p) methods. These are shows excellent agreement with experimental data's. The C-C-C in-plane bending vibrations are always occurs below  $700\text{ cm}^{-1}$ , these bands are quite sensitive to change in the nature and position of the substituent's [12]. In 4PMP, the C-C-C in-plane bending vibrations observed at FT-IR  $742$ ,  $702$ , and  $686\text{ cm}^{-1}$  in FT-Raman and predicted C-C-C out-of-plane bending vibrations are also in good agreement with the measured values. The ring torsion was calculated at  $55$  and  $57\text{ cm}^{-1}$  in B3LYP/6-31+G (d) and B3LYP/6-311++G (d, p) methods, respectively.

### O-H Vibrations

The O-H group gives rise to three vibrations such as stretching, in-plane bending and out-of-plane bending vibrations. The O-H group vibrations are likely to be the most sensitive in the environment, so they show pronounced shifts in the spectra of the hydrogen bonded species. The O-H stretching vibration is normally observed in the region around  $3500\text{ cm}^{-1}$  [13]. In the present case, a medium-strong broad absorption at  $3272\text{ cm}^{-1}$  in FT-IR and  $3272\text{ cm}^{-1}$  in FT-Raman spectrum are assigned to O-H stretching vibration. The stretching vibrational wavenumber of free O-H is practically unchanged, while that of the bond O-H is red shifted. The red shift of the O-H stretching wavenumber is due to the formation of strong O-H...O hydrogen bonds by hyper-conjugation between aldehydic oxygen lone electron pairs and O-H anti-bonding orbital's. The in-plane bending of O-H vibrations observed in the region  $1250\text{--}1150\text{ cm}^{-1}$  [14] taken as the second criterion. This is evident for the absorption at  $1175\text{ cm}^{-1}$  is nearly correlated with experimental spectrum. The out-of-plane bending vibrations are usually occurring in the region  $720\text{--}590\text{ cm}^{-1}$  [15]. In 4PMP, out-of-plane bending vibrations are found at  $652\text{ cm}^{-1}$  in FT-Raman spectrum. These assignments are validated by the literature.

### C-O Vibrations

The C-O stretching vibrations in alcohol and phenol produce a strong band in the region  $1260\text{--}1000\text{ cm}^{-1}$  [16]. In present case, a medium FT-IR spectrum at  $1248\text{ cm}^{-1}$  has been assigned to C-O stretching vibration. The corresponding vibration appears in the FT-Raman spectrum at  $1072$ ,  $1037\text{ cm}^{-1}$ . The theoretically computed values of B3LYP level are  $1248\text{ cm}^{-1}$  and the bands of level are at  $1038\text{ cm}^{-1}$ . These are shows excellent agreement with experimental data's. The in-plane bending vibration often occurs with sharp and strong intense band in and FT-Raman bands observed at  $446$  and  $415\text{ cm}^{-1}$ . The theoretically computed values are at  $925\text{ cm}^{-1}$  shows good agreement with experimental values. The calculated out-of-plane bending vibrations are computed at  $262\text{ cm}^{-1}$  by B3LYP method with 6-31+G (d) and 6-311G++ (d, p) basis sets, respectively.

### C–H Vibrations

The aromatic C–H stretching vibrations of hetero aromatic structures are expected to appear in the region 3100–3000 cm<sup>-1</sup> [17]. The nature of substituent's can not affect the bands much in the region. In the present study, 3068, 3045, and 2962, cm<sup>-1</sup> was assigned to C–H stretching vibration in FT-Raman spectrum. They show good agreement with theoretically computed values at 3200, 3102 and 3052 cm<sup>-1</sup> in B3LYP and at 3192, 3093 and 3041 cm<sup>-1</sup> in methods using 6-311G++ (d, p) basis set. The observed wavenumbers of C–H stretching vibrations are also in good agreement with the measured values and literature data [18]. The C–H in-plane and out-of-plane bending vibrations generally lie in the region 1300–1000 cm<sup>-1</sup> and 1000–675 cm<sup>-1</sup> [19], respectively. In accordance with above literature data the weak band observed in FT-IR spectrum at 1197, 1116, 1096, 1058, 1034, and 988 cm<sup>-1</sup> in FT-Raman spectra. The weak to strong FT-IR bands observed at 900, 895, 834, and 808 cm<sup>-1</sup> and FT-Raman bands observed at 625 cm<sup>-1</sup> are assigned to C–H out-of-plane bending vibration. They are good agreement with literature values [20]. The B3LYP and calculated wavenumbers at are correlated with experimental values.

### CH<sub>2</sub> Vibrations

For the assignments of CH<sub>2</sub> group frequencies basically Six fundamental can be associated to each CH<sub>2</sub> group namely CH<sub>2</sub> symmetric stretch, CH<sub>2</sub> asymmetric stretch, CH<sub>2</sub> Scissoring and CH<sub>2</sub> rocking which belongs to in-plane bending vibrations and to out of plane bending vibrations, viz., CH<sub>2</sub> asymmetric stretching vibrations are generally observed in the region 3000–2900 cm<sup>-1</sup>, while the CH<sub>2</sub> symmetric stretching vibrations were appearing between 2900–2800 cm<sup>-1</sup>. [21] For our title compound, the CH<sub>2</sub> asymmetric and symmetric stretching vibrations are observed at

3026 and 2930 $\text{cm}^{-1}$  in FT-Raman Spectrum. The calculated asymmetric and symmetric  $\text{CH}_2$  stretching vibrations are 3068, 2992, and 2994 $\text{cm}^{-1}$  at FT-IR and FT-Raman spectra of 4PMP.

In the present study, the  $\text{CH}_2$  bending modes follow, in decreasing wave number, the general order  $\text{CH}_2$  scissoring >  $\text{CH}_2$  wagging >  $\text{CH}_2$  twisting >  $\text{CH}_2$  rocking. Since the bending modes involving hydrogen atoms attached to the control carbon atom falls into the 1450–875  $\text{cm}^{-1}$  range, there is extensive vibrational coupling of these modes with  $\text{CH}_2$  deformations particularly with the  $\text{CH}_2$  twist. It is notable that with  $\text{CH}_2$  scissoring and rocking wave sensitive to the molecular conformations.

The four bending modes of  $\text{CH}_2$  groups are scissoring, rocking, wagging and twisting for EPAP molecule, are assigned to within the range. The  $\text{CH}_2$  scissoring mode identified at 1488  $\text{cm}^{-1}$  in FT-IR and  $\text{CH}_2$  wagging mode observed at 1348  $\text{cm}^{-1}$  in FT-Raman spectrum [22]. The peaks observed at 934  $\text{cm}^{-1}$  in both spectra is assigned to  $\text{CH}_2$  rocking, which is coupled with C–C stretching vibration and  $\text{CH}_2$  twisting mode observed at 423  $\text{cm}^{-1}$  in FT-IR spectrum. All these calculated values are in good agreement with the observed values.

#### 4.2. Mulliken Atomic Charges

The Mulliken atomic charges calculation has an important role in the application of quantum mechanical calculations to molecular system [23] because of atomic charges effect dipole moment, molecular polarizability, electronic structure and more a lot of properties of molecular systems. Mulliken atomic charges calculated at the DFT/B3LYP/6-31+G (d) and /6-311++G (d, p) methods is presented in Table 4.

Table 4

Mulliken's population analysis of 4-(phenylmethyl)phenol performed at B3LYP/6-31+G (d) and B3LYP/6-311++G (d, p) methods.

S. No.	Atom No.	Mulliken's Atomic charges	
		B3LYP/6-31+G (d)	B3LYP/6-311++G (d, p)

---

It is worthy to mention that C<sub>4</sub> atom is more acidic due to more positive charge. The Mulliken atomic charges of the phenol group hydrogen atom H<sub>8</sub> are higher than the aromatic group and methyl group hydrogen. It denotes that the phenol group hydrogen atoms are more acidic than the aromatic and methyl group hydrogen atoms, however that the high value 0.862808 and 0.593193e for C<sub>4</sub> in B3LYP and methods with 6-31+G (d) and 6-311++G (d, p) basis set. The O<sub>7</sub> atom exhibit high negative charge is -0.696869 and -0.266469 for B3LYP method with 6-31+G (d) and 6-311++G (d, p) basis sets. The results can however better represent in graphical 3D form as given Fig. 7, respectively.

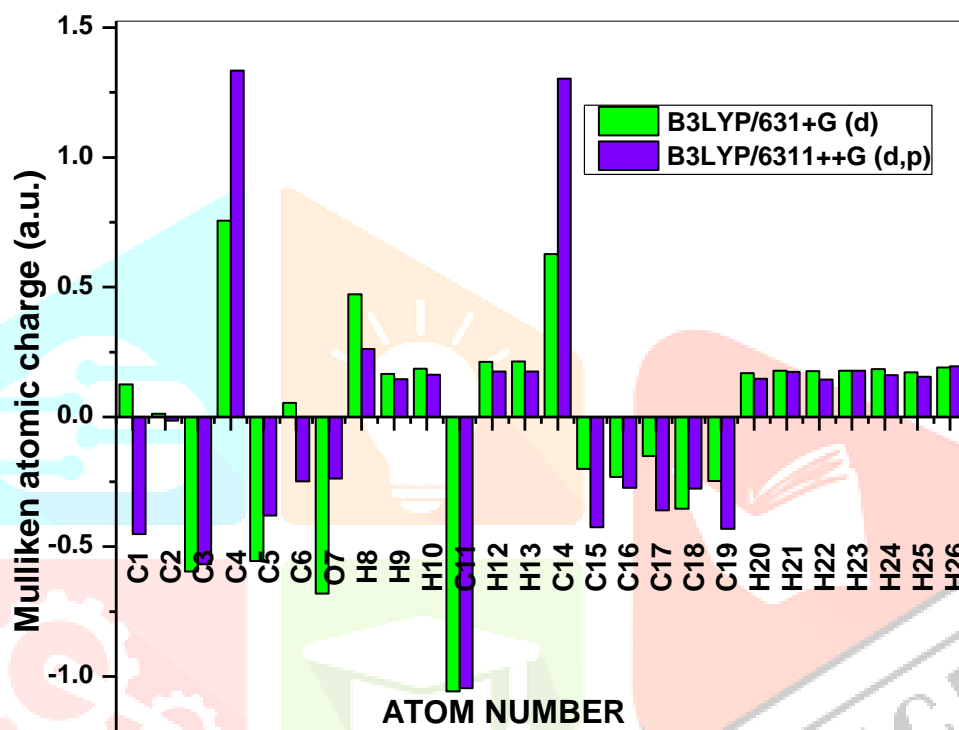

Fig. 7. Comparative Mulliken's plot by B3LYP/6-31+G (d) and B3LYP/6-311++G (d, p) Level 4-phenylmethyl) Phenol

### 4.3. HOMO-LUMO analysis

The most important Frontier molecular orbital (FMO) such as highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) plays a crucial part in the chemical stability of the molecule [24]. The HOMO represents the ability to donate an electron and LUMO represents the ability of accept an electron. The energy gap between HOMO and LUMO also determines the chemical reactivity, optical polarizability and chemical hardness-softness of a molecule. A molecule with a small frontier orbital gap is more polarizable and is generally associated with a high chemical reactivity, low kinetic stability and is also termed as soft molecule [25].

According to the results, the 4PMP contains 47 occupied molecular orbitals and 339 unoccupied molecular orbitals. The HOMO and LUMO energies calculated at B3LYP method with 6-31+G (d) and 6-311++G (d, p) basis set are presented in Table 5. The HOMO and LUMO pictures and their orbital energies are calculated by B3LYP/6-31+G (d) and 6-311++G (d, p) are shown in Fig.8, respectively. The positive phase is red and negative one. It is clear from the Fig. 8, shows that the isodensity plots for the HOMO and LUMO are well localized and the intra-molecular interactions

mostly occurred within the ring. The transition HOMO-LUMO which has a relative energy gap of 6.824 eV and 6.328 eV in B3LYP method with 6-31+G (d) and 6-311++G (d, p) basis sets, respectively.

Table 5

Comparison of HOMO, LUMO energy gaps and related molecular properties of 4-(phenylmethyl) phenol at B3LYP/6-31+G (d) and B3LYP/6-311++G (d, p) methods.

Molecular properties	Energy (a.u.)	Energy gap (eV)	Ionization potential (I)	Electron affinity (A)	Global Hardness (n)	Electro negativity ( $\chi$ )	Global softness ( $\nu$ )	Chemical potential ( $\mu$ )	Global Electrophilicity ( $\omega$ )

LUMO	0.00343								

Fig. 8. The molecular orbitals and energies for the HOMO and LUMO of 4-(phenylmethyl) phenol

### Global reactivity descriptorS

Based on the density functional descriptors, global chemical reactivity descriptors of title molecule such as ionization potential ( $I$ ), electron affinity ( $A$ ), chemical potential ( $\mu$ ), electronegativity ( $\chi$ ), global hardness ( $\eta$ ), global softness ( $\sigma$ ) and global electrophilicity ( $\omega$ ) values can be described as followed [26]. In simple molecule orbital theory approaches, the HOMO energy ( $E_{\text{HOMO}}$ ) is related to the ionization potential ( $I$ ) by Koopman's theorem and LUMO energy ( $E_{\text{LUMO}}$ ) has been used to estimate the electron affinity ( $A$ ) [27].

$$\left[ \begin{array}{l} \text{Ionization potential (I)} = - E_{\text{HOMO}} \\ \text{Electron affinity (A)} = - E_{\text{LUMO}} \end{array} \right]$$

The average value of the HOMO and LUMO energies is related to the electronegativity ( $\chi$ ) defined by Mulliken [23].

$$\left[ \text{Electronegativity } (\chi) = \frac{(I + A)}{2} \right]$$

In addition, the HOMO and LUMO energy is related to the hardness ( $\eta$ ) and softness ( $\sigma$ ) [28].

$$\left[ \begin{array}{l} \text{Global hardness } (\eta) = \frac{(I - A)}{2} \\ \text{Global softness } (\sigma) = \frac{1}{\eta} \end{array} \right]$$

Parr et al. [29] defined global electrophilicity ( $\omega$ )

$$\left[ \text{Electrophilicity } (\omega) = \frac{\mu^2}{2\eta} \right]$$

where  $\mu$  is the chemical potential takes the average value of ionization potential ( $I$ ) and electron affinity ( $A$ ) [30].

$$\left[ \text{Chemical potential } (\mu) = - \frac{(I + A)}{2} \right]$$

The electronic chemical potential is the parameter which describes the escaping tendency of electrons from an equilibrium system. Thus the frontier molecular orbital analysis also provided the details on chemical stability, chemical hardness and electronegativity of the molecule in B3LYP/6-31+G (d) and B3LYP/6-311++G (d, p) methods are presented in Table 5, respectively.

### 4.5. Molecular electrostatic potential (MEP)

At any given point  $r(x, y, z)$  in the vicinity of a molecule, the molecular electrostatic potential,  $V(r)$  is defined in terms of the interaction energy between the electrical charge generated from the molecule electrons and nuclei and a positive test charge (a proton) located at  $r$  [31]. The molecular electrostatic potential (MEP) is related to the electron density and a very useful descriptor for determining sites for electrophilic and nucleophilic attack as well as hydrogen-bonding interactions [32]. For the systems studied the molecular electrostatic potential values were calculated as described using the equation:

$$V(r) = \sum \frac{Z_A}{|R_A - r|} - \int \frac{\rho(r')}{|r' - r|} dr$$

where the summation runs over all the nuclei  $A$  in the compound and polarization and reorganization effects are neglected.  $Z_A$  is the charge of the nucleus  $A$ , located at  $R_A$  and  $\rho(r')$  is the electron density function of the molecule. The molecular electrostatic

potential MEP map for positive and negative sites of the title molecule as shown in Fig.9. The MEP is a plot of electrostatic potential mapped onto the constant electron density surface. Different values of the electrostatic potential are represented by different colors. Red represents the regions of the most negative electrostatic potential and blue represent the regions of the most positive electrostatic potential. Potential increases in the order red < orange < yellow < green < blue. The color grading of resulting surface simultaneously displays molecular size, shape and electrostatic potential value which are very useful in research of molecular structure with its physiochemical property relationship [33]. It is clear from the figure, while regions having the negative potential are over the electronegative atoms (oxygen atoms), the regions having the positive potential are over the hydrogen atoms. As can be seen from the MEP of the title molecule, more reactive sites are near O–H group, the regions having the most negative potential over the oxygen atoms C<sub>19</sub> the negative potential values are -14.7385 a.u. indicates the strongest repulsion (electrophilic attack). A most positive region localized on the hydrogen atoms C<sub>4</sub> and its values are 0.33180 a.u. indicates the strongest attraction (nucleophilic attack), respectively.

Charges (e)	Atoms	V (r) (a.u.)
-0.6505	O7	22.2743
-0.3267	C <sub>19</sub>	14.7385

## 5. CONCLUSION

In the present work, the optimized molecular structure of the stable conformer, electronic properties, vibrational frequencies and intensity of vibrations of the title compound have been calculated by DFT/B3LYP/6-31+G (d) and DFT/B3LYP/6-311++G(d, p) methods level calculations. The optimized geometric parameters (bond lengths and bond angles) are theoretically determined and compared with the experimental results. The vibrational FT-IR and FT-Raman spectra of the 4PMP are recorded and on the basis of agreement between the calculated and experimental results. The frontier molecular orbital's (FMOs) and HOMO–LUMO analysis are industrially important of the molecule. The calculated HOMO–LUMO and frontier orbital energy gap values along with their 3D plot are presented in this study for better understanding of charge transfer occur within the molecule the first order hyperpolarizability value of the title compound is approximately 1.36 and 1.46 times greater than the value of urea in both basis sets. The MEP map shows the negative potential sites are on oxygen and hydrogen atoms as well as the positive potential sites on the molecule.
