Abstract

Background
Musculoskeletal disorders have become increasingly common worldwide during the past decades. Prevention of Work-related Musculoskeletal Disorders (WMSDs) is becoming crucial and requires the identification and modification of risk factors. In terms of location, the lower back was the most commonly reported site of discomfort. Individual characteristics of the worker such as gender, age, stature, physical condition, strength and occupational factors such as awkward postures, prolonged repetitive movements, static postures, stress, intense work schedules etc or combination of the above factors lead to musculoskeletal disorders in workplace. Flight attendants are people whose job requires them to stand, walk, kneel, bend, stoop, reach, movements, static postures, stress, intense work schedules etc or combination of the above factors lead to musculoskeletal disorders in work place. Flight attendants are people whose job requires them to stand, walk, kneel, bend, stoop, reach, lift heavy objects from the floor to above shoulder level heights and push and pull equipments and service meal carts. The Airline industry is one of the most rapidly growing industries in India, and due to the lack of literature on airline attendants, work-related back pain, their relation with musculoskeletal risk factors and the type of their occupation needs to be established. So the purpose of this study is to identify self-reported prevalence and to analyse the risk factors in relation to low back pain among flight attendants.

Materials and methods:
The present study was a one-time cross-sectional survey study, which included a sample of 145 flight attendants. Subjects of either gender satisfying the inclusion criteria were taken up for the study. An informed consent was taken before the procedure. Each subject’s demographic data was collected. The Questionnaire was given to the study population.

Results: Descriptive statistics was used to find out the prevalence of LBP. Chi square test was used to test the association of LBP to age, gender and number of working years. Independent t test was used for the comparison of difference in mean age and number of working years among those with LBP and without LBP group. Confidence interval was computed as 95%. Low back pain prevalence in flight attendants was 69.7%. Results also showed association between age and LBP (p<0.001), which was very highly significant and association between work experience and LBP (p<0.001) which also indicated a very high significance. This difference in mean between age, years of work among those with LBP and without LBP (p<0.001) was found to be statistically highly significant. There was no correlation found between gender and LBP.

Conclusion: Flight attendants have a high prevalence of LBP. Age and work experience are the two factors closely related with LBP. There was no association found between gender and LBP.

Key words: Low back pain, flight attendants, prevalence, musculoskeletal disorders

INTRODUCTION
Musculoskeletal disorders have become increasingly common worldwide during the past decades. They are the significant contributors to work related disability and a major cause of sick leave. By definition, musculoskeletal disorder refers to the presence of injury or pain with the muscles, skeletal systems, joints, connective tissue (ligaments and tendon), associated nerves or soft tissue. Pain is the most common symptom in this disorder and may present in a distinct localized manner or as an ongoing ache over a broad anatomical region. The World Health Organization defines MSDs as “disorders of the muscles, tendons, peripheral nerves or vascular system not directly resulting from a acute or instantaneous event (e.g., slips or falls). These disorders are considered to be work-related when the work environment and the performance of work contribute significantly, but are only one of a number of factors contributing to the causation of a multi-factorial disease.”

The past two decades have witnessed a sharp rise in the incidence of work-related musculoskeletal disorders (WMSDs). Prevention of WMSDs is becoming crucial and requires the identification and modification of risk factors. Individual
characteristics of the worker such as gender, age, stature, physical condition, strength, etc. may contribute to the occurrence of these musculoskeletal disorders. Moreover, the specific occupation and work organization may be the source of ergonomic hazards. Awkward postures, prolonged repetitive movements, intense work schedules or fast work pace represent important risk factors for WMSD. In terms of location, the lower back was the most commonly reported site of discomfort. Risk factors for pain in lower back included duration of standing, waist-bending and weight-lifting. Mechanical Low Back pain (MLBP), non-mechanical pain and visceral disease are some of the various known types of Low Back Pain. It is caused due to an unspecified injury to the lumbar spine and hence, it represents up to 97% of patients with this problem. Point prevalence ranges from 12% to 33%, one year prevalence ranged from 22% to 65% and life time prevalence ranged from 11% to 84%. Low back pain is the largest single cause for about 12.5% of all sick leaves.

The purpose of this study is to identify self-reported prevalence and to analyse the risk factors in relation to low back pain among flight attendants

**METHODOLOGY**

The study included a sample size of 145 flight attendants between 25 to 35 years of age working in Jet Airways, Bangalore. *Inclusion criteria:* Flight attendants working for more than 3 years in the airline industry, Age group: 25 to 35 years, Both males and females were included in the study. *Exclusion criteria:* History of any back injury in the past 1 year, Any known neurological disorders, Pre-existing musculoskeletal pathology of the lower back.

**Materials used:** A self-administered questionnaire. This questionnaire was divided into two groups: For people with LBP and for people without LBP. The questions for people with LBP was divided into 6 sections that included the onset and description of pain, subject’s personal characteristics such as age, sex and years employed in occupation, respondent’s job history, physical risk factors at work and general health status, a section about sleep, functional activities and the social life. The questions for people without LBP was divided into 3 sections namely, subject’s personal characteristics such as age, sex and years employed in occupation, the job characteristics, functional activities and the social life. The questionnaire was distributed to physiotherapists who specialize in musculoskeletal and LBP, they evaluated the questionnaire for aspects related to LBP assessment such as specificity. The questionnaire was also given to senior flight attendants who evaluated the questionnaire for appropriateness and their daily work activities and representation of their daily living activities that may predispose them to low back pain. The questionnaires were collected back and revised again. The revised questionnaires were validated again by the same group of people and the face validity was thereby obtained.

**Procedure of Data collection** - Subjects of either gender satisfying the inclusion criteria were taken up for the study. The purpose of the study was explained to the subjects. An informed consent was taken before the procedure. Each subject’s demographic data was collected. The Questionnaire was given to the study population A self-administered questionnaire for LBP comprising of several questions on low back trouble was distributed to the selected subjects. The questionnaire was very user friendly and was designed to take approximately 10 minutes to complete. A variety of questions were used which involved yes or no response, rating the symptoms, etc. In addition, the subjects were requested to mark the location of the symptoms suffered on a pictorial diagram. Subjects with LBP were further investigated with a YES questionnaire and subjects without LBP were investigated with a NO questionnaire. There was strictly no interaction allowed between the subjects. The filled questionnaire was collected at the same time and the data was taken for the statistical analysis.

**Data Analysis** Descriptive statistics was used to find out the prevalence of LBP. Chi square test was used to test the association of LBP to age, gender and number of working years. Independent t test was used for the comparison of difference in mean age and number of working years among those with low back pain and without low back pain group. Confidence interval was computed as 95%.

**RESULTS**
Table 1: Prevalence of low back pain

<table>

Independent t test, df=143

From the above table mean (±SD) age among those with low back pain and without low back pain was 30.16 (±2.28) and 26.61(±1.67) respectively. Similarly for years of work it was 6.90 (±2.34) and 3.57 (±0.63) respectively. This difference in mean between age, years of work among those with low back pain and without low back pain was found to be statistically highly significant.

Graph 1: Association of age, work experience with LBP
**Discussion** The purpose of this study was to find out the prevalence of low back pain among flight attendants and to analyze the risk factors in relation to low back pain. In the current study, total sample size of 145 subjects was selected from Jet Airways, Bangalore after they met with both inclusion and exclusion criteria. Hence, in the present study the total sample of 145 subjects (n=145) ranging in age from 25 to 35 years with a mean age of 26.61 years ± 1.67 years, mean working experience of 3.57 years ± 0.67 years for people with no pain and with a mean age of 30.16 years ± 2.27 years, mean working experience of 6.90 years ± 2.34 years for people with pain were included in the study. All the subjects were distributed with the self-administered questionnaire and were collected on the same day. The results found were as follows. The prevalence of self-reported LBP was 69.7%. Out of 145 subjects, 101 subjects reported of having LBP at least once in the past 6 months.

In the present study, the higher prevalence of LBP was found in higher age groups. Out of 145 subjects, 101 subjects who reported of having LBP had a mean of 30.16 years and 44 subjects who reported of having no back pain had a mean of 26.61 years. By using an Independent t test, comparison of mean age between the groups was statistically highly significant (p<0.001) indicating association between age and low back pain. The study also investigated the role of age and work experience in relation to low back pain. The results show that low back pain increased with increasing age. Age has been proposed as a prognostic factor. A review by Malchaire J et al., revealed that the association between age and musculoskeletal problem was evident in half of the studies which included age as a risk factor.

Out of 101 subjects who reported of having LBP, 64 were females and 37 were males. On analyzing the data for gender and LBP using Chi square test, the association between gender and LBP was not statistically significant. Erdil M et al. found that the prevalence of low back pain is highest between the ages of 35 and 55 years and there are no significant gender differences. This may be because the workloads of male and female flight attendants are similar in nature and may be below the threshold level of work where gender differences such as strength and endurance may affect the results of the study.

**CONCLUSION** Flight attendants have a high prevalence of LBP of about 69.7%. Age and work experience are the two factors closely related with LBP. Risk factors such as repetitive movements, heavy and frequent lifting along with awkward postures (bending, twisting), prolonged standing, intense work schedules may be associated with a risk of developing LBP. There was no association found between gender and LBP.
