ABSTRACT

The coordination complexes of Co (II), Ni (II) and Cu (II) were prepared from tridentate Schiff base. The Schiff base ligand was synthesized by the condensation of 3-ethoxy-4-hydroxy benzaldehyde with 2-amino butanoic acid. The ligand and its metal complexes were characterized by elemental analysis, molar conductance, electronic spectra, IR spectra, NMR spectra, electrical conductivity and magnetic susceptibility. The transition metal complexes are colored and stable in air. In the metal complexes the metal-ligand found to be 1:1. A sharp band at 1625 cm⁻¹ is characteristics of the azomethine group present in the Schiff base ligand. This band was shifted to lower frequency (1585 – 1605 cm⁻¹) in all the metal complexes, which indicates the coordination of the azomethine nitrogen to metal ion in complexes. The IR spectra of the free ligand having phenolic (-OH) group showed a broad band at 3450 cm⁻¹, the disappearance of this band in metal complexes indicates the deprotonation of the hydroxyl group and coordinated through oxygen atom. A band at 1690 cm⁻¹ is assigned to ν(C=O) stretching frequency of ligand, which is shifted to lower regions (1612-1640 cm⁻¹) in metal complexes indicating the coordination of oxygen atom with metal ion after deprotonation of -COOH group. The molar conductivity data of the complexes in DMSO solution indicates they are non-electrolytic nature. On the basis of magnetic susceptibility and electronic spectral data Co (II) and Ni (II) complexes have tetrahedral geometry, while Cu (II) complex square planar geometry has been suggested. The synthesized Schiff base complexes exhibit higher antimicrobial activity than the free Schiff base ligand.

Keywords: Schiff base, metal complexes, 3-ethoxy-4-hydroxybenzaldehyde, antimicrobial activity.
1. INTRODUCTION

Metal complexes have been receiving considerable attention for many years, due to their interesting characteristics in the field of biological systems and material science. A large number of Schiff base and their metal complexes may exhibit the properties like to reversibly bind oxygen, transfer of an amino group as nano precursors and varied complexing ability. Schiff bases are formed when condensation of primary amines with active carbonyl compounds under specific conditions and were first synthesized by Hugo Schiff in 1864. Schiff bases are represented as \( R – CH = N – R^1 \) where \( R \) and \( R^1 \) may be alkyl, aryl or heterocyclic. Azomethine functional group present in Schiff bases. Due to effective conjugation Schiff bases of aromatic aldehydes are more stable than aliphatic aldehydes. Ketones react slower than aldehydes in condensation reaction due to steric hinderance. Schiff bases are generally unidentate, bidentate, tridentate, tetradentate and polydentate ligands to form stable complexes with transition metals. Schiff bases are effective ligands due to presence of azomethine group. Schiff bases derived from aromatic carbonyl compounds and primary amines have more applications in the fields of biological, analytical, inorganic chemistry, catalysis and optical materials. Schiff base ligands have donor atoms may be nitrogen, oxygen or Sulphur which provided binding sites through non-bonding electrons. The presence of \(- CH = N \) group in the transition metal complexes which contains donor nitrogen atom is responsible for stability, reactivity and biological activity of complexes. 2-Amino butanoic acid is a non-proteinogenic 6-amino acid, which is a derivative of alanine with a side chain that is one carbon longer than the alanine side chain. It is synthesized through the transamination of oxo butyrate and is non-ribosomal peptides. Transition metal Schiff base complexes are wide applications in medicinal chemistry, catalysis, polymerization reactions, dyes, corrosion, plant growth regulators and analytical chemistry. Due to chelation transition metal Schiff base complexes are more stable and have wide applications in antibacterial, antifungal, antiviral, anticancer, and anti-inflammatory. Schiff base ligands acts as chelating ligands and their biological activity enhanced on coordination. The present aim of the work is to synthesize a Schiff base derived from 3-ethoxy-4-hydroxy benzaldehyde and 6-amino butanoic acid and to prepare its transition metal complexes, characterize them and study their antibacterial and antifungal activities.

2. MATERIALS AND METHODS

All the chemicals and solvents used for present work of Anal-R grade and used without further purification. Metal salts were purchased from Loba Chemie. 3-Ethoxy-4-hydroxybenzaldehyde and 2-amino butanoic acid were obtained from Sigma-Aldrich. The percentage (%) of Co, Ni and Cu were determined by EDTA complexometric titration. The elemental analysis (C, H and N) data was obtained using 2400 CHN Perkin-Elmer elemental analyzer. The molar conductivity of the complexes in DMSO solution (10\(^{-3}\)M) were measured by using DI-909 digital conductivity meter. The IR spectra of the ligand and metal complexes were recorded on Shimadzu FTIR spectrophotometer using KBr disc. The magnetic susceptibility data were measured by Gouy method using Hg [Co ( SCN)\(_4\)] as a calibrant. The electronic spectra of the complexes were recorded by using Shimadzu model UV-1601 spectrophotometer in DMSO solution.

**Synthesis of Schiff base ligand**

The Schiff base ligand was prepared by the condensation of 3-ethoxy-4-hydroxybenzaldehyde (1.66g, 0.01 mol) with 2-amino butanoic acid (1.03g, 0.01 mol) in ethanol (25 ml) and the mixture was refluxed for 2 h. After cooling, the yellow coloured solid was obtained. Which was filtered and washed with ether and recrystallized from ethanol and dried in a vacuum desiccator.
Synthesis of metal complexes

The metal complexes were prepared by mixing (50 ml) ethanolic solution of CoCl₂.6H₂O / NiCl₂.6H₂O / CuCl₂.2H₂O with the (50 ml) ethanolic solution of Schiff base in a metal-ligand ratio 1:1. The resulting mixture was refluxed on water bath for 2-3 h. The complex obtained in each time was cooled, filtered and washed with ether and recrystallized with ethanol and dried under reduced pressure over anhydrous CaCl₂ in a desiccator.

3. RESULTS AND DISCUSSION

The physical properties and analytical data of ligand and its metal complexes are listed in Table 1. All the metal complexes are colored, solid and stable at room temperature. They decompose on heating at high temperature. The metal ligand ratio in all the metal complexes have 1:1. Schiff base acts as tridentate ligand. The molar conductivities in DMSO solution show that all metal complexes are non-electrolytic nature.

FTIR Spectra

The important infrared spectral bands of the Schiff base and its metal complexes are listed in Table 2. The coordination sites in chelate compounds are determined by the IR spectra of free ligand compared with that of complexes. The IR spectrum of the synthesized Schiff base ligand showed absorption band at 1625 cm⁻¹ is characteristic of azomethine (>-C=N) group present in the Schiff base ligand. This band was shifted to lower regions (1583-1605 cm⁻¹) in the metal complexes, which indicates the bonding of the metal to the azomethine nitrogen. The spectra of metal complexes exhibit broad bands in the range of 3412 – 3442 cm⁻¹ indicating the presence of coordinated water molecule. The IR spectra of the ligand having phenolic -OH group showed a broad band at 3450 cm⁻¹. The disappearance of this band in metal complexes suggests deprotonation of the phenolic –OH group after its chelation with the metal ion. A medium intensity ligand band at 1290 cm⁻¹ (phenolic ν(C-O)) which gets shifted to a lower frequency (1270 – 1236 cm⁻¹) in the complexes, which suggests the participation of phenolic oxygen in coordination with metal ion. Two new bands appearing in the low frequency range 425-435 cm⁻¹ and 518-565 cm⁻¹ are indicate the formation of M-O and M-N bond in the complexes. A band at 1690 cm⁻¹ is assigned to ν(C=O) stretching frequency of ligand, which is shifted to lower regions (1612-1640 cm⁻¹) in metal complexes indicating the coordination of oxygen atom with metal ion after deprotonation of -COOH group. Thus, the IR spectrum indicates that the ligand in all the metal complexes behaves as tridentate and the binding sites are azomethine nitrogen, phenolic oxygen and carboxylate oxygen atom in the metal complexes.

Electronic absorption spectra

The electronic absorption spectra of metal complexes were recorded in DMSO as solvent. The electronic spectrum of the [CoL(H₂O)] complex showed three absorption bands around 14200 cm⁻¹,17300 cm⁻¹ and 22000 cm⁻¹, which assigned to the transition ⁴A₂(F) → ⁴T₁(P). The value of the magnetic moment of Co-complex was 4.61 B.M, tetrahedral geometry is suggested. The electronic spectrum of the [NiL(H₂O)] complex showed three absorption bands around 15250 cm⁻¹,21200 cm⁻¹ and 26300 cm⁻¹, which assigned to the transition ³T₁(F) → ³T₁(P) and LMCT respectively. The value of the magnetic moment of Ni-complex was 3.61 B.M, tetrahedral geometry is suggested. The electronic spectrum of the [CuL(H₂O)] complex showed two absorption bands around 17850 cm⁻¹ and 31300 cm⁻¹, which assigned to the transition ²B₁(g) → ²A₁(g) and LMCT respectively. The value of the magnetic moment of Cu-complex was 1.81 B.M, square planar geometry is suggested.
Antimicrobial activity

The synthesized ligand and its complexes were screened for their in vitro antibacterial activity against Escherichia coli and Staphylococcus aureus and antifungal activity against Aspergillus niger and Candida albicans by minimum inhibitory concentration method. The minimum inhibitory concentration profiles of all the compounds against bacteria and fungi are presented in Table 3. The MIC values indicated that all the complexes show more activity compared to the free ligand against microorganisms, and this activity is found to be enhanced on coordination with the metal ions. This also can be explained on the basis of Tweedy’s chelation theory and the effect of the metal ion on the normal cell processes. It was further noted that the delocalization of electrons over the whole chelate ring enhanced the lipophilicity of the complexes. This increased lipophilicity enhanced the penetration of the complexes into lipid membrane and blocking the metal sites on enzymes of microorganisms. The antimicrobial activities show that Cu- complex is more active than the other metal complexes.

4. CONCLUSION

The Schiff base derived from 3-ethoxy-4-hydroxybenzaldehyde and 2-amino butanoic acid and its metal complexes of Co(II), Ni(II) and Cu(II) were synthesized and characterized by analytical and spectroscopic techniques. The Schiff base ligand acts as tridentate and coordinated with the metal ion through azomethine nitrogen and oxygen atoms of phenolic and carboxylic group. The analytical data show the composition of the metal complexes to be [M(L)(H₂O)], where L= Schiff base ligand and M = Co(II), Ni(II) and Cu(II). The molar conductivity data of the complexes in DMSO solution indicates they are non-electrolytic nature. On the basis of magnetic susceptibility and electronic spectral data Co (II) and Ni (II) complexes have tetrahedral geometry, while Cu (II) complex square planar geometry has been suggested. The synthesized Schiff base complexes exhibit higher antimicrobial activity than the free Schiff base ligand.
