Abstract:
To create some outstanding new ideas of innovation during Pandemic, this paper reveals an augmented study of modified robust fuzzy clustering approach to detect the unusual outliers. Outlier Detection, an unsupervised learning used to detect complex dataset to identify perpetual outliers using membership function to tolerate the uncertainty. The first stage aims to estimate auto-detection of noise reduction, incorrect data points and so on as perpetual outliers. The second stage aims to determine the characterization of utilized input parameters of unending outliers using FCM (Fuzzy C-means Clustering) method to find FOF (Fuzzy Objective Function). This method enhances accuracy, efficacy over similarity measure and performance efficiency that assessed over some UCI repository datasets. Experimental results and statistical evaluation shows effectiveness of detecting perpetual outliers.

Keywords: Outliers, fuzzy, clustering, Fitness, Perpetual, FOF, Characterization

1. Introduction:
During Pandemic, the situation is worst and uncertain to predict the future events. Outlier detection is also an important and complex task due to its uncertainty intolerance. Outlier known as anomaly identifies the extreme points from the dataset [1]. Fuzzy clustering is the suitable method for handling the uncertainty. Due to technology development, rare events happen due to technology advancement. Data is pre-processed to reduce the noise and focused on predictions to reveal highly desirable task. No of clusters is determined for the iterations. Distance is evaluated using Euclidean measure. Fuzzy objective function is measured based on the threshold value. The Cluster validation is determined by the optimal no of clusters. All the input parameters are characterized using a threshold value. It is evaluated by no of intensive clusters in ‘inliers’ and in ‘outliers’. The degree of membership belongs from 0 to 1. Accuracy is very close to cluster input parameters of detected prototypes. During Characterization, a random learning of false data point and dominating capability of influence structure is fixed.

2. Literature Survey
Outliers which may treated as error results in underestimation of uncertainty tolerance. Outlier analysis is studied from charu.C.Aggarwal[1][3][7]. The various types of anomaly detection and characteristics is studied from Chandola, Banerjee and Kumar[2]. Clustering techniques are identified by Aggarwal, Chandan and Reddy[3]. Outliers identity is studied from Hawkins[4][9]. How to detect the outliers in real time application using fuzzy clustering is studied from Rajalakshmi and Madhubala[5]. R programming by Yanchang Zhao[9]. Fuzzy set is studied from Bezdek[11] and Klir and Yaun[10].
The prediction model is used to calculate residuals of estimating various waves of fuzzy outliers. From the study, the non-adherence of protocol stemmed up by the characterization of extreme datapoints. The number of clusters indicate efficient generalization over learning of fuzzy objective function by less computational effort. It uses membership value, cardinality value, and cluster validation indices.

A modified approach using feature based indexing for the labeled patterns with high membership function is considered for generalization [7]. A generalized fuzzy index method and novel constraint function of membership is understand by the study [8]. A detailed study of estimating ERR and ERR for z-score is demonstrated in [14]. How the psych and z-curve package is evaluated in R-script to study the outlier fitness as well from [17][18][19].

3. About the software packages used:

R tool (r 4.0.2 version) is used to analyse the outliers using fuzzy clustering. “psych” package is installed for factor analyzing the Perpetual outlier fitness. William Revelle[17][18], clearly estimates ERR(Expected Replicability Rate), EDR(Expected Discovery Rate) and ODR(Observed Discovery Rate) using the packages psych and z-curve.Confirmatory factor analysis is estimated by using fuzzy clustering, iclust(), item cluster analysis used to partition space of the fitness rather than space of the variable. It explains an implementation of z-curves and method for estimating replicability rates (ERR) and expected discovery rates(EDR) on finding fitness, metrics etc

Algorithm
Phase I:
Step 1: Initialize no of clusters ‘k’
Step2: Compute fuzzy membership matrix ‘U’
Step3: calculate fuzzy centers ‘Vj’ until j is minimum
Step4: Estimate the centroid of each cluster center ‘c’
Step5: Update the minimum distance to each cluster using Euclidean distance
Step6: Auto-detect the centers to identify farthest neighbor
Step7: If the object has no neighbor, define it is outlier

Algorithm
Phase II:
Step 1: Initial the fuzzy variables
Step2: Calculate the sum of all the objects which has similarities
Step3: Fix a random point between two similar clusters (say for eg. Between 0.5 and 0.7, 0.6 as random intensity values)
Step 3a: Compare the random object with threshold value.
Step 3b: If it is equal to threshold, move to next neighbour cluster
Step 3c: Repeat step 3a until the value is below threshold
Step4: At the end, extreme points from the old cluster to is used to detect the perpetual outlier of new cluster
Step5: Depending on threshold value, outlier is identified.
Step6: The objective function is obtained from new cluster is called FOF (Fuzzy objective function)

4. Experimental Results

RStudio 4.0.2 is used for estimating statistical analysis. Packages used are “psych” and “zcurve”, where zcurve developed by Frantisek Bartos on 27,September -2020 to detect the accuracy of outliers[17][18][19]. By installing zcurve package, we used density method to find the increase number of iterations and decrease number of criterion for the dataset stock_data. Estimation of ERR(Expected Replicability Rate) and EDR(Expected Discovery Rate) is shown below.
Table 1: Estimation of z-curve 2.0 density algorithm

<table>
<thead>
<tr>
<th>Dataset</th>
<th>ERR</th>
<th>EDR</th>
</tr>
</thead>
<tbody>
<tr>
<td>iris</td>
<td>NA</td>
<td>NA</td>
</tr>
<tr>
<td>Stock_data</td>
<td>0.6135274</td>
<td>0.5064392</td>
</tr>
<tr>
<td>Advertising</td>
<td>NA</td>
<td>NA</td>
</tr>
</tbody>
</table>

Using zcurve package, we used density method for the version 1 to increase the number of iterations for the dataset stock_data. Estimation of ERR(Expected Replicability Rate) and EDR(Expected Discovery Rate) is shown below.

Table 2: Estimation of z-curve to increase the number of iterations

<table>
<thead>
<tr>
<th>Dataset</th>
<th>ERR</th>
<th>EDR</th>
</tr>

<tbody>
<tr>
<td>iris</td>
<td>NA</td>
<td>NA</td>
</tr>
<tr>
<td>Stock_data</td>
<td>0.6479701</td>
<td>0.5046194</td>
</tr>
<tr>
<td>Advertising</td>
<td>NA</td>
<td>NA</td>
</tr>
</tbody>
</table>

Using zcurve package, we furnished the details regarding total number of starting fits and the means of mixture components. Estimation of ERR(Expected Replicability Rate) and EDR(Expected Discovery Rate) is shown below.

Table 3: Estimation of z-curve to increase the number of starting fits and change in means of mixture component

<table>
<thead>
<tr>
<th>Dataset</th>
<th>ERR</th>
<th>EDR</th>
</tr>
</thead>
<tbody>
<tr>
<td>iris</td>
<td>NA</td>
<td>NA</td>

<td>NA</td>
</tr>
</tbody>
</table>

In the fourth table, we comprised the z-curve fitness to simulate z-statistics. The estimation of ERR(Expected Replicability Rate), EDR(Expected Discovery Rate) and ODR(Observed Discovery Rate) is shown below.

Table 4: Estimation of z-curve to simulate z-statistics and z-fitness for stock_data dataset

<table>
<thead>
<tr>
<th>z-score</th>
<th>Estimation Range (0.64 – 5.51)</th>
<th>Percentage</th>
<th>CI-(Confidence Interval)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERR</td>
<td>0.82</td>
<td>95%</td>
<td>0.73,0.89</td>
</tr>
<tr>
<td>EDR</td>
<td>0.55</td>
<td>95%</td>
<td>0.24,0.89</td>
</tr>
<tr>
<td>ODR</td>
<td>0.85</td>
<td>95%</td>
<td>0.80,0.89</td>
</tr>
</tbody>
</table>

In the fifth table, we calculated the power components of z-score for the value of alpha from 0 to 1.( 0.05 to 0.999)
Table 5: Estimation of $z$-curve power components

<table>
<thead>
<tr>
<th>Power to $z$-score</th>

Figure 1: No of clusters after removal of noise in stock_data dataset
Figure 2: The Estimation of Using Expectation Method (EM) via Expectation Method (EM), for lower Confidential interval (l.CI) and upper Confidential interval (u.CI) for replicable iteration is as follows.

Figure 3: The Estimation of KD2 via Expectation Method (EM), for replicable iteration
Figure 4: z-curve (EM via EM)

Figure 5: z-curve (KD2 via DENSITY)
Figure 6: Using Expectation Method (EM).

From the figure (1) - (5) z-curve is estimated for many iterations of stock.dat the model converged at the rate of 0.09215481 with (25+66) iterations and (24+22) iterations with 92% detection of outliers.

5. Conclusion

Towards the contemporary world of pandemic, researchers are making very close and accuracy to the machine understandable efforts rather than human. Using utilization factor, the number of observation comes under the study is more efficient for the outcome of the outliers. Estimating is based on replicability rates of statistical testing such as t-test, F-test, chi-square test, Z-test, ERR and EDR. It simulates the robustness of outliers that undergoes uncertainty as significant to the margin. FOF(Fuzzy Objective Function) determines the utilization factor by fitting random points of clusters and detecting the perpetual outliers (disabilities) to fade the replicability fitness over the outliers to normalize. The test results shows a complete consent to measure the values of outliers using fuzzy clustering approach.
