Abstract – For most of the countries now-a-days the national agenda is the agricultural production because of rapid climatic changes that affects the crop growth like vegetables, fruits, grains and insect infestation. Because of rapid climatic changes it is becoming hard to achieve maximum yield of the crops, because of this many countries are seeing greenhouse as a very good option to guarantee their agricultural results. In this paper we have proposed a smart greenhouse monitoring system that consists of different sensors which monitor the total area of the greenhouse and these sensors mainly include temperature and humidity sensor, light controlling (LED) sensor, soil moisture and PH controlling sensor. The system consists a facility of fire alert system and SMS alert system which will be displayed on the user's phone. Dataset used for this system has different kinds of pictures of numerous plants which are taken from different angles and the plants captured are both healthy and affected. This system has the ability to capture images and store in the database and predict results based on that data. The system uses Convolution Neural Network (CNN) which helps in training the model and detecting the disease. This survey paper gives information about the system which is equipped with numerous IoT-based applications to control and monitor greenhouse and help in building a suitable agriculture environment.

Key Words: Internet of Things (IoT), smart greenhouse, Convolution Neural Network (CNN), image processing, IOT sensors, Machine learning.

I. INTRODUCTION

Agricultural productions are the important part in the welfare of society and economic exchange between countries. Therefore, food demand is continuously increasing. The agriculture sector can produce only 3% more than required because farmers have postponed seeding different crops on their lands because of climatic changes. Therefore, to counteract undesirable environmental conditions and crops damages because of infestations of insects, in some cases, farmers use fertilizers and pesticides to speed up the planting and harvesting of crops. In some cases farmers use seeds and fertilizers without the knowledge to manage them on a huge scale. As a result of the wrong use of fertilizers and pesticides, the quality of the land decreases as well as the crops grown on it lose essential nutrition also.

A Greenhouse, which is a exceptionally outlined home like structure. This gives a more controllable and monitorable environment to a better crop growth, transplantation, harvest generation and product yields. In today's world, for developing yields, more space of land which has been utilized for commercial purpose, housing area space is accessible. The cost-effective farming such as new blossoms, organic products and vegetables generation is the utilization of Greenhouse development in many tropical nations. The surety of ideal atmosphere development conditions which is to attain to the high return at great quality, low natural dependency and low cost is the effectiveness of plant creation inside Greenhouse which depends

fundamentally. Parameters like light, humidity, temperature, soil moisture, pH must be controlled ideally where the given certain criteria through water pump, warming, ventilation and lighting are used to attain certain objectives. By regular monitoring and controlling of these geographical parameters which gives a significant data that is related to individual impacts of the elements differently towards acquiring the most extreme creation of harvest. The present difficulty in Greenhouses is to control environment factors. Temperature changes quickly, In Greenhouse as a result, fluctuations relying upon sun powered UV light level, soil moisture levels and outside temperatures. Poor natural quality frequently bought by the high humidness and poor light intensity. Improving the efficiency of labours by entitle them for the more important tasks, electricity charges, empowering producers and directors to settle on better administration choices and to invest more on the energy dealing with procedures can be decreased by practicing exact control over the system.

We have proposed a system which can read the parameters from the environment which is identified within the Greenhouse and will be controlled manually or by Android app which we will developed. The cloud will store data for future use. If any climate values fluctuate the precautionary measures will be taken by the user. Image processing is widely used in agriculture for the images taken by remote sensing devices such as cameras and other devices. Only original images are taken for training the plant disease identification model. The training and testing of the models are implemented in Google colab by importing necessary packages using TensorFlow. The proportion of dataset used for training and testing is 80:20. An accuracy of 95% was obtained as the maximum and 72% was obtained as the minimum, with the average accuracy of prediction being 85%. By the usage of the previous technologies we were able to recognize different kinds of diseases. The usage of a huge dataset which was a combination of images for a healthy and unhealthy leaves and the fruit or vegetables was also beneficial.

IV. METHODOLOGY

1) MPC (Model Prediction Control) and PID(Proportional Integral Derivative) :

MPC is the Mathematical Optimization Algorithm used to predict the future behavior of the system. It is also used to control the actions performed by the actuators known as process control.

PID is used to regulate the output of the system taken from the feedback of sensors .

2) Digital Twin and ANN :

Digital Twin is used for predicting real time entities in a digital form . Also it is used to process large amount of sensor data .

ANN is used for analyzing the data from remote sensors . It increases the accuracy and effectiveness of the product

3) Sensor-Based Approach:

This system uses multiple sensors to sense the data. On the data sensed all the parameters are dependent. Thereforesning the accurate value is the most critical part of the system.

4) SVM and k-Means:

This are the supervised machine learning algorithm used for classifying the images as healthy or unhealthy and also grouping them into different categories of diseases.

v. CONCLUSION

The green house monitoring and controlling system is proposed to address the modern problems of greenhouse systems. Proposed system does monitoring of various parameters such as temperature, humidity, soil moisture and etc.

The systems helps to find out abnormal conditions using above parameters. The system controls the greenhouse by taking remedial actions on the abnormal results of parameters. This data insights are useful for the quality production of crop and is used to predict the health of crop. CNN model is used to identified the plant leaf disease. Where the dataset of plant leaf trained which has leaf images.

The proposed systems also reduces the labor cost which is used for manual controlling and monitoring of green house. Proposed system can be integrated in future. System can extend to use it to outside of the greenhouse system on a wider range. Efficient camera can be introduced for clearer images for better accuracy. Data storage limitations can be overcome by using new age technology such as fog computing. Using fog computing data access will be easier. Security features can be added.

Further advancements in smart glove technology can lead to more accurate and robust sign language detection. It can be integrated into educational tools and platforms. Smart gloves can empower deaf or hearing-impaired individuals to live more independently. This technology can also facilitate communication in different settings, such as schools, workplaces, hospitals, and public spaces.

In many countries and regions, various sign languages and dialects exist alongside the standard national sign language. Smart gloves could adapt to these regional variations, enhancing communication for deaf individuals in different local communities. During emergency situations or disasters, it's crucial for first responders to communicate effectively with all members of the community, including those who use local sign languages. Smart gloves can be adapted to assist in such scenarios.
