Abstract: The availability of a system, machine or equipment for production or service is the key parameter to improve the productivity of any organization. The failures cannot be avoided completely but can be reduced through proper maintenance programme which can be developed if one can predict the occurrence and mode of failure in advance. Hence, it is the responsibility of managers to keep track of their machines or equipment and make available for maximum run hours with minimum failures. This will also help them in improving the reliability of the machines/equipment. This study is taken up to identify the failure and run modes of TSRTC buses to improve the availability and the customer satisfaction. The data regarding the bus failures and run hours for the period of 32 months has been collected and trend is analysed using graphical methods and also tested for presence of correlation.

Index Terms - Trend, Failure mode, Availability, Time between failures (TBF), CTBF, Run Time

I. INTRODUCTION

The Public Transport Corporations run by the state government are playing a vital role in serving the public for their day to day transportation needs i.e. for going to schools/ colleges, offices and on business works. The major part of the country's economy is from the transport systems like airways, railways, metro rail, roadways, waterways etc. They also created employment to many people directly and indirectly. Private buses, taxis, self-owned cars and auto- rickshaws are now competing with the state run public transport systems which have become threat to their existence. In the context of the competition, it is must that the state run transport operators should be available for failure free service and gain the confidence of customers with safe and satisfactory service.

The failure control of buses or equipment is the challenging task of the Managers of any organization. It is very much essential to maintain the good condition of the buses or equipment in order to provide the failure free service in the field. The maintenance programs to make the system available are of great significance due to a competition and overall operating costs. The performance of system depends on maintenance schedules, working conditions/ environment, technical skills of operators, etc. When the failures of system are low, the efficiency of organization improves and vice versa. So efforts are always needed to reduce the failure rate of the systems.

The failure of systems or equipment is unavoidable but cann be minimized with effective maintenance schedules, which can be designed only if one can predict or assess the occurrence of failure. This can be done by close monitoring of trends of failures. This trend analysis can be used to judge the life cycle characteristics of systems maintenance schedules, replacement analysis and also for designing the reliability of the system.

This study is carried out at one of the bus depots (Uppal) of TSRTC to evaluate the failure and run patterns. The aim of this paper is to investigate and identify whether the buses are deteriorating or improving based on the past run and failure data of buses.

II. OBJECTIVES OF THE STUDTY

The objectives of the present study are as follows

- To investigate failure and run patterns of buses by collecting and analyzing the data.
- To suggest a suitable maintenance program for maximising run hours.
- To improve the availability and reliability of buses.

III. FAILURE AND FAILURE PATTERNS

The Failure is the inability of a system or equipment to perform the specified function under given conditions. It can be non conformance to some predefined performance.

Failures can be as follows:

a) Based on time/age of equipment: (i) Early failures at infant stage (ii) Random failures or rare event failure (iii) Old age or wear out failures b)Based on volume of failure: (i) Small failures (ii) Minor failures (iii) Major failures (iv) Catastrophic failures

c) Based on mode of failure: (i)Sudden failures (ii) Progressive failures (iii) Retrogressive failure (iv) Gradual failures.

Failure Patterns: All systems irrespective of whether they are mechanical, Electrical etc are assumed to behave in the same manner. with reference to failure that occur, they will have any one of these three behaviours: (i) Rate of failure is decreasing (DFR) i.e. The condition of system is improving (ii) Rate of failure is constant (CFR) The condition of system may or may not be consistent but it gives the average output required.(iii) Rate of failure is increasing (IFR) i.e. The condition of system is deteriorating.

IV. TREND ANALYSIS

The objective of Trend analysis is to understand whether the system is improving or deteriorating which can be done by analyzing the past failure data.

Trend can be three types: (i) Positive trend (ii) Negative trend and (iii) No trend

(i) Positive trend:- his is due to New or infant stage of system or can be due to effective maintenance program. It implies that the system is improving with the time.

(ii) Negative trend:-This is due to frequent or long failures. It can be due to old age or worn out parts. It implies that the system is deteriorating with the time. This trend affects the productivity.

(iii) No trend: This shows the failure times or neither increasing nor decreasing. It means the system is experiencing constant failure rate. It implies that the failure behaviour if independent of the time.

Methods of Trend Analysis: There are two methods of testing the trend 1.Graphical methods for trend setting (a) Cumulative plot Test (b) Eye Ball analysis 2. Analytical trend test: (a) Laplace Test (b) MIL-HDPK-189Test

V. METHODOLOGY

In this paper, the following methods are used to test the trend:

a. Cumulative plot Test: It it tested by plotting the cumulative TBF(time between failures) against the Cumulative number of failures. The interpretations are made as follows: (i) if the derived curve is concave upward, it implies that the TBF's are becoming shorter and shorter which means the system is deteriorating.

(ii) If the derived curve is concave downward, it implies that the TBF's are longer which means the system is improving.

(i) If the derived curve is linear, it implies that there is no trend, which means the system is to be further analysed by statistical distributions.

b. Eye Ball Analysis: Eye are passed through chronological TBFs and search is done to know if there is any r increase or decrease of failures. If TBFs show increasing trend towards end, then it indicates decreasing failure rate.

Alternatively, by tabulating the cumulative frequency and divide total period into equal groups(class interval) of 5-10. If increasing failure is observed for each period, it indicates increasing failure rate and so on.

c. Test for presence of serial Correlation: It can be tested by plotting ith TBF against (i-1)th TBF and the interpretations are made as follows: (i) if the plotted points scattered randomly without any pattern, it is interpreted that the TBF's are free from serial correlation (ii) if pattern exists, then it reveals serial correlation, then the TBF's are plotted at greater lags to search for it.

d. Analysis with Karl Pearson's coefficient of Correlation test: This is tested with i^{th} TBF v/s (i-1)th TBF and i^{th} TBF v/s (i-2)th TBF and so on. The degree of association can be interpreted with coefficient of correlation (r) which ranges from -1 to +1 via zero. (i) Close to -1 is negative association i.e. increase in first quantity induces the decrease in second quantity (ii) Close to +1 is positive association i.e. increase in first quantity induces the increase in second quantity (Proportional) (iii) Close to zero indicates poor correlation that is, both the quantities are independent.

VI. DATA COLLECTION AND ANALYSIS

The data is collected from the Uppal depot (Hyderabad) of TSRTC. The depot plies an average of 120 buses everyday in two shifts (8 hrs/shift). The data (i.e. TBF, no. o f breakdowns, late supplies, frequency of failures, total breakdown hours, total run hours, Total kilometres lost, etc) is gathered from Daily register, Breakdown register, Cancellation register and personal discussions with depot officials. The data was collected for the period of April 2015 to Nov 2017 (i.e. for 32 months) and is tabulated (Tables 1 & 2) for further analysis and evaluation.

| S.n o | Month & Year | No of Break downs | Cum breakdowns | B.D.Kil o Meters Lost | No of Late Supplys | L.S.Kil o Meters Lost | Tota l Kilo Meters lost | Schduled Kilometers | Operated kilometers |

Graph 3b: Plot showing cumulative frequencies for different groups

Graph 5: Plot showing the trend between *i*th failure and (*i*-1)th failure

VII. RESULTS AND DISCUSSIONS

The data from table 1 is plotted between number of failures per month during the year April 2015 to November 2017. It can be observed that the failure rate almost remained the same during this period. It is evident from graph 2 that the number of kilometers lost has decreased although the failure rate increased. This may be due to the availability of spare buses at the depot.

www.ijcrt.org © 2018 IJCRT | National Conference Proceeding NTSET Feb 2018 | ISSN: 2320-2882 National Conference On Trends In Science, Engineering & Technology by Matrusri Engineering College & IJCRT

From the tabulated data in Table 1 and Table 2, the following factots are evaluated. The frequency of breakdown is 3 per 10,000 kms and the bus utilization is 96 percent. From Eye Ball Analysis graphs 3(a) and 3 (b), it is observed that TBF's are increasing for the first three periods which indicates a decrease in failure rate. Later there is a decrease in TBF's showing an increase in failure rate.

The number of failures vs cumulative failure hours is plotted for trend analysis is shown in Graph 4. The curve is concave downward indicating that the availability of buses is increasing.

The scatter plot i.e. graph 5 drawn between the trend between ith falure and (i-1) th failure indicates that TBF's are scattered and hence show they are free from serial correlation.

From Table 5, coefficient of correlation 'r' is calculated as 0.17 using the following equation1. The positive value indicates close association between two successive failures.

 $r = \sum (X^*Y)/(\sqrt{\sum X^{**2} \sum Y^{**2}})$ ----- Eqn 1.

VIII. CONCLUSIONS

- The cumulative plot (from april2017 to Nov 2017) shows that the curve is concave downward, which indicates that the bus availability is improving. It is also evident from the fact that the failures have come down by 28% in 2017-18 compared to 2016-17.
- In spite of less failures and availability of bus hours, the operational efficiency has come down (56.85 lakh kilometers operated in 2017-18 as against 65.65 lakh kilometers in 2016-17). It is suggested that the traffic department should initiate suitable action.
- Average breakdowns are 20 per month, though the scheduled maintenance is carried out, which require more attention and focus of the maintenance department.
- The positive value of Coefficient of Correlation (r= 0.17), shows there is proportional association between two successive failures. The random scattered plot indicates that the TBFs (Time between failures) are free from serial correlation.
